Mr. Henry Yates, a widely-known and respected engineer and contractor, of Brantford, died at his residence in that city on the 22nd of July. The late Mr. Yates was for many years chief engineer of the Grand Trunk Railway, and supervised the carrying out of several large railway contracts.

EXPANSION OF CHIMNEYS.

It does not often happen that facilities are afforded for exact measurements to be made of the expansion and contraction of a factory chimney. It is generally admitted that boiler chimney shafts should not be attached to the walls of any important building on account of the risk of cracking the walls by the expansion of the heated brickwork; but it is not very easy to obtain reliable information respecting the amount of such expansion, and some persons have doubts whether brickwork really expands or contracts when heated. An unusual opportunity of making measurements on this point has recently occurred at Newcastle-upon-Tyne. The boiler chimney of the college was erected five years ago, and has been in constant use during the interval. As originally constructed it stood alone, 60ft. from the college building, 99ft. high from the concrete foundation, and 100ft. from the ground level. To the height of 33ft. from the ground an interval firebrick flue was constructed, with an air space of 3in. between it and the shaft. The upper 57ft. of the shaft was built of stock brick only, and had a uniform diameter of 6ft. 2in. externally, while the internal flue increased from 3ft. 11in. to 4ft. 8in. in diameter, the strictly cylindrical character of the exterior giving the chimney the appearance, when looked at from a distance of fifty yards or more, of being trumpet shaped, and larger at the top than at the bottom. During the last few months a casing of ornamental brickwork has been erected around the chimney, but independently of it, so that the casing of the shaft forms one of four octogonal turrets surrounding the Royal Jubilee Exhibition Tower, and guarding the principal entrance to the college quadrangle. The near completion of the brickwork surrounding the chimney afforded the opportunity of observing from the top of the casing any movement of expansion or contraction of the chimney itself. As the boiler fires are generally drawn or allowed to die out on Saturday afternoon and relighted on Monday morning, the chimney has an opportunity of cooling down during about forty hours and observations made from the top of the casing wall showed a contraction of the chimney of five millimètres, or 2in., during that time. As the surrounding wall was still about 6ft. below the top of the chimney when the measurements were made, and as the first 33ft. of the shaft remained practically cold on account of the air space between it and the centre flue, it may be taken that the length of brickwork in which the expansion took place was about 50 feet. According to this a shaft 100ft. high should expand 4in. when in use. The measurement was only of a preliminary character made for the purpose of determining whether it would be safe to allow the decorative work at the top of the turret to rest partly on the outer casing and partly on the internal flue, and the result showed conclusively the desirability of keeping the chimney shaft entirely independent of any other structure.

C. H. Mortimer Esq.
Canadian Architect
& Builder

Dear Sir, We have pleasure in testifying to the Satisfactory results we have had from advertising in your journal. Inquiries have reached us from Halifax to Vancouver traceable directly to this medium

Yours truly
Elliott & Son

THE PERSPECTIVE PROCESS.

On first learning the meaning of a picture, it would naturally strike the mind, says the Illustrated Carpenter and Builder, that a sure and easy method of carrying any point from its position in space to its position in the picture would give anyone the power of drawing the outline required. Such a process might be laborious, but it would put the whole design within possible reach. This method would be an excellent one for learners to begin with, previously to entering on the use of vanishing points; it would be something like learning to count with pebbles before entering on the common rules of arithmetic. Even without diagrams it may be possible to give such a description of the process as will enable some who have never attempted anything before to put a few simple figures into perspective. Let the picture plane, which suppose transparent, be spread out before the spectator, reaching down to the ground, and bounded on the right by a side wall, which extends both before and behind it. Every point which is to be drawn has a point directly below it on the ground, which call its ground-point; and a point directly opposite on the side wall, which call its side point. All the ground points make, when properly jointed, what the architect calls a plan; all the side points are elevation. The picture would be called a section if points were taken on it opposite to the points to be represented; instead of this a point is carried to its place on the picture along a line drawn to a certain point in front of the picture, which represents the eye of the spectator. This eye-point has also its ground-point and its side-point. The picture has its ground line and its side line, and every point in the picture has its ground-point upon the ground-line and its side point upon the side line. A picture-point is known when we know where the ground-point is by its distance from the side line, and where the side-point is by its distance from the ground line. To lay down a given point on the picture, draw a line from its ground-point to the ground point of the eye; that line meets the ground-line of the picture in the ground point of the picture point required. In the last sentence for ground read side, and we see how to find the side point of the picture point in the side line of the picture. Two lines being drawn on a paper perpendicular to one another, the right side of the paper may represent the side wall laid flat on the ground by turning round its ground line, and the left side may represent the ground plane. The two sides of the line which separates the upper part of the paper from the lower represent the ground line and side line of the picture. Take another paper, or another part of the same paper, draw two perpendicular lines, lay down the ground and side picture points by taking their distances from the paper on which they have been found, and the points of the picture may at once be put in their places. This is an explanation of the principle of a picture and an exhibition of a sufficient method of construction; that is of sufficient power, but not of sufficient facility; every point requires the drawing of three lines.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2⅞ × 3	2⅞	131,000	15,188	
C	2 1/16 × 3	2⅞	130,000	14,751	
D	3 × 3	2⅞	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have a large quantity of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

THE term "joiner" does not mean a carpenter, says the Canadian Presbyterian. It means a man or woman who joins all the societies and associations in the community.

THE twenty-eighth annual convention of the American Institute of Architects will be held on the 15th, 16th and 17th of October in New York city. A number of valuable papers are promised for the occasion.

WE print in this number an interesting letter from Mr. G. F. Stalker, in advocacy of a change of method in the designing and erection of government buildings. The attention of our readers has already been called to the favorable reception of the Bill introduced in the United States Congress to provide for throwing open to competition among the leading architects of that country work of this character. This is the system which has prevailed for some time with satisfactory results in Great Britain. The subject is one in which Canadian architects should feel an interest, and which might fitly receive some consideration at the approaching annual conventions of the Province of Quebec and Ontario Associations of Architects. We would be pleased also to print the individual opinions of architects on the subject.

ON every hand there are indications of a revival of trade. The settlement of the American tariff question has had a beneficial influence on commerce in the United States, which is certain to extend to Canada. As the result of the free exportation of Canadian lumber into the United States market, we may expect to witness great activity in the manufacture of rough and finished lumber in Canada, and this must have a beneficial influence on every department of trade. During the depression through which we have been passing, manufacturers and merchants have reduced stocks to the lowest possible point. With increased purchasing ability will come a revival in manufacturing and other industrial enterprises. It is now too late to expect much improvement in conditions this year, but the indications for 1895 seem to be of a very encouraging character.

A PIECE of scaffolding work requiring more than ordinary care was put up in Toronto last month by Messrs. Dill & O'Hearn, contractors, for painting the spire of St. Patrick's church on William street. A scaffold more than sufficient for paint work was necessary to gild the large cross at the top. The height from the ground to the top of the cross is one hundred and sixty nine feet. The construction of the spire prevented access to the inside to a greater height than one hundred and ten feet. Here, through four small window openings, built up beams 6"×12" were placed projecting level five feet, the inside ends made secure by blocking to the spire timbers. On these a platform was laid three feet wide all around. All the scaffolding material was hoisted up to this height with a rope and pulley outside. On the platform, directly over the beams, four corner poles were footed and blocked with diagonal braces to each other and back through the window openings. The balance of the work was carried up in the usual way with poles lashed together and stagings at every six feet of its height. The completed work was severely tested by a heavy storm on Sunday, Sept. 2nd, but stood uninjured. Considerable difficulty was experienced in laying the gold leaf on account of high winds, but this was overcome by pitching a tent twelve feet high on the top staging to cover in the cross while that part of the work was being done.

THE Commissioners of the London Exhibition of 1851, of whom the Prince of Wales is chairman, at a recent meeting decided to contribute £200 a year for five years in addition to a previous payment of £300, in aid of the maintenance of the department for investigating and testing the natural products of the Colonies and India at the British Institute. An English contemporary makes the statement that the Institute "does little but dine and wine its members and tea loungers at sixpence a head." If this be the case the grant in question is not likely to be of much benefit to the colonies.

A NEW application of iron frame and fire-proof construction is likely to find employment in building city residences. A New York architect, Mr. Manly N. Cutter, has recently secured estimates on three houses, showing that this method can be used with very little increase in cost, the difference being only about $200 on a house worth nearly $10,000. This difference would be fully made up by the increased floor space which the iron construction would afford. Mr. Cutter's estimates were based on wrought steel uprights, girders and floor beams, with a woven wire netting fastened to these for walls and floors. For exterior walls it is proposed to use 4 inch brick work outside and a terra cotta lining inside the netting; for party walls, terra cotta on both sides of the wire netting. Concrete floors between iron beams to receive the wooden covering, and ceilings plastered on metal lath. The roof would be constructed same as the floors, and the basement story built in the usual manner up to the cast-iron bed plates for the steel uprights.

ARCHITECTS will note with satisfaction every indication of a growing interest on the part of the general public in architecture. The great amount of attention bestowed on the Chicago World's Fair buildings, by visitors and the press, so enlivened public interest in architecture as an art, as to exert a permanent influence in the direction of a demand for good architecture in all kinds of buildings. The recent publication in some of the leading popular magazines of special articles and illustrations of architectural subjects is another strong indication of an increasing public appreciation of the importance of the subject. We are surprised to see in the Engineering Magazine the opinion expressed that it may be seriously questioned whether the publication of such articles is a healthy indication of a growing and widening taste in architectural knowledge on the part of the general public. Publishers of the great magazines are not in the habit of using material unless in their opinion it is of a kind for which there will be the best demand, and their judgment in this matter is to our mind a satisfactory proof of an awakening public interest in architecture. We should be glad to know what our contemporary would consider the kind of indications on this line to which value could be attached.

THE Dominion Parliament at its last session acceded to the request of the labor organizations that one day in each year be constituted a statutory holiday, to be known as "Labor Day". The object of the organized labor bodies in asking for this legislation was no doubt to direct public attention by this means to themselves and the issues for which they are contending. The idea from this standpoint is a good one. Apart from its advertising value in this respect, however, the holiday is not necessary, as there were previously more holidays on the statute books than the frugal workman desired. The wisdom and right of any particular class of the community to arrogate to themselves the title of "workingmen," is also called in question. Such a step is likely to accentuate the lines of distinction between employers and employees, which many had hoped would in future be less tightly drawn. It is hoped that this result may not follow, but that by mutual effort, conducted on reasonable lines, the employer of labor and the workman whose only capital is his ability to labor, will seek to bring about conditions which will be in the highest degree equitable and satisfactory. The labor organizations will also doubtless find it necessary in the future to seriously consider ways and means of bringing into more harmonious relationship to themselves the great number of non-union workmen. There is a growing bitterness of feeling between union and non-union workmen, which is the outgrowth of arbitrary action on the part of the former, and which, if not removed, will eventually bring about the entire overthrow of the labor organizations. In short, the times demand the adoption of more reasonable methods on the part of all concerned in the solution in all its phases of what has come to be known as "the labor question."

WE print in this number of the ARCHITECT AND BUILDER the letter of another advertiser who has proved the value of this Journal as a medium through which to reach the purchasers of building materials. The abundance and value of the testimony which is being published month by month should convince the most skeptical manufacturer and dealer in such materials, that his business would be helped by a standing announcement in the pages of this Journal. Since the publication of the testimonial letters, in our recent issues, we have been authorized to insert the advertisements of several firms, some of whom were never previously represented in our columns and others who had become weary in well doing and had withdrawn their advertisements. Within the past week we received from a leading firm of architects in Montreal a letter in which they stated that they were inviting tenders for architectural iron work for a certain building, that they had written to the several firms whose advertisements they found in the CANADIAN ARCHITECT AND BUILDER, and requesting to know if we could furnish them with the names and addresses of other manufacturers in the same line. We hope that architects generally will follow the example of this firm, by writing us when requiring materials which they do not find advertised. On this subject the American Architect correctly says: "Architects need all the resources that can be offered to them in the way of novelties in rolled shapes of iron and steel, new modes of constructing fireproof floors and ceilings, new methods of beam protection, improved cements, new marbles, new qualities and colors of brick and terra cotta, and they want to know by simply turning over a leaf in the current number of their professional journal, not by trying to hunt up circulars or calendars, who are the principal terra cotta makers, where are the principal stone and marble quarries, who does concrete work and whether there is any recent improvement in such work, who does copper roofing, and whether it has occurred to any manufacturer, in these days of cheap copper, to furnish roofing plates of low brass or some similar alloy, which would be cheaper, harder and better than pure copper. Certainly if manufacturers and dealers in such materials expect to have their goods used on a large scale, they must be used through the architects, since all important building contracts are made in accordance with some architect's specification, and in order to have them used in this way they must be brought to the attention of the architects who write the specifications, in such manner that when the specifications are being written the name of the thing desired can be ascertained, and inserted in the specification, at a moment's notice."

SOME of our neighbors in the State of New York have taken alarm at the scope of the various plans on foot to utilize the water power of Niagara Falls, and at the unlimited character of the licenses already granted to divert water from the Falls for this purpose. A committee of the constitutional convention of the State of New York now sitting, has presented a report dealing with this matter, which is being opposed by representatives of the power companies. It is to be hoped that the subject will be thoroughly thrashed out. Certainly on investigation it does seem as if there were some grounds for the action which has been taken, and a doubt whether we have not gone a little too fast and too far in granting franchises. It is difficult to get reliable figures on the flow of water over Niagara Falls, but taking those given in the Encyclopedia Britannica—18,000,000 cubic feet per minute, with a fall of 164 feet on the American side and 150 feet on the Canadian side—the gross power would be a little more than 5,250,000 H. P. With such an enormous power to draw from it would seem that we might cut and come again without risk of any appreciable effect upon the natural beauty of the Falls. But on examining the franchises granted a little in detail it appears that if they are availed of to the full extent of the projectors' anticipations, that there would result a serious impairment of the volume of water now passing over the Falls. The present tunnel on the American side is only 100,000 H. P. capacity, but the full projected power on that side is stated to be 500,000 H. P., which at the present available head of 140 ft., would require about 200,000,000 cubic feet of water gross. On the Canadian side, by agreement approved by the Ontario legislature, the power company has the right to take water for a power station occupying a tract of land not to exceed 100 ft. by 1200 ft. The present station on the American side which is of 50,000 H. P. capacity, measures 68 by 200 ft., therefore the limit of the Canadian concession would be about 300,000 H. P., or about 1,200,000 cubic ft. of water. These two principal undertakings would therefore amount to 3,200,000 cubic feet, which the electric railway on this side, the old hydraulic canal on the other side, and existing private and town rights on both sides, would easily swell to 3,600,000 cubic ft., or 20% of the natural flow as given in the Encyclopedia Britannica. One fifth reduction in the volume of Niagara Falls, would involve a ruin of their natural beauty, which would be a disgrace to us as one of the custodian nations of this wonder of the world. Such a catastrophe is only a possibility, and a remote possibility. Unless further powers are granted, on the Canadian side, the concession is probably limited to less than the amount estimated above, by the provision in the agreement that the water shall be led off by the natural channel between Cedar Island and the mainland. But even the possibility of such a catastrophe in the far future, fully justifies the action which has been taken in New York. No shadow of excuse could be urged for destroying Niagara Falls for the enrichment of a few capitalists and a locality. We are far from the time when any pressure of the population on our national resources could justify such utilitarianism.

WE often hear the statement that it is a favorable time to carry out building enterprises during periods of general business depression, such as we have lately experienced, on account of the low prices for material and the eagerness of men for work enabling contractors to tender much lower than usual. There is much truth in this, and it is a perfectly natural condition, but contract prices are in many cases cut lower than there is any reason for within the limits of legitimate business. No building should be erected for less than its value, which should include the cost of all material and labor with a reasonable profit for the contractor. The whole question of prices for building work of ordinary kind seems to be in a badly mixed condition. People have grown into the habit of expecting too much for their money in this kind of work and are inclined to believe it can be done for whatever they choose to pay if they can only get hold of a contractor who will tender as low as possible. Evils too numerous to mention are the result, and if they are lessened or cured it must be by effort on the part of the more intelligent contractors. Briefly we wish to notice a few of the conditions which might be improved by the right kind of effort. When prices are too low in any business there is sure to be an attempt to lower the quality of material or workmanship, and nowhere is this plainer to be seen than in the building trades. Every contractor worthy of the name should stand for first-class work and fair prices. If the contractor for one trade does really good work and the work of another trade forming part of the same job be inferior, the good work must suffer by its proximity to the bad. Contractors can generally ill afford to carry out work for less than value, but it is most likely to be the one who is least able to stand a loss who will cut prices. Nor is the loss to him alone, but because he is unable to handle his work in a business-like way, all other trades are liable to be interfered with and put to actual loss. Contractors should be quite as particular as to who they are associated with as co-contractors on a job, as they are in the selection of their own foreman or other help. There are many items which the contractor should include in estimating besides the cost of material and labor, such as the use of capital invested, risks by accident, bad weather, fluctuation in prices, wear and tear of plant, his own time, etc. After these are allowed for, he should have a profit of at least ten per cent., but we believe comparatively few contract prices are sufficient to leave even this moderate margin. No cure-all remedy can be applied to every case of the low price disease, but if contractors were well organized and working under some carefully prepared code they would be able to remove the greater part of these difficulties. In this way only their combined influence can be made available, and much could be done to prevent the business being handled at unreasonably low prices.

ILLUSTRATIONS.

CHURCH AND PRESBYTERY OF THE PARISH OF THE SACRED HEART, MONTREAL.

The church was built in 1882 from plans by Mr. Jos. Venne, architect, now of the firm of Perrault, Mesnard & Venne, who are now building the presbytery adjoining it. It is of Montreal limestone, roofed with slate; and with a plain and tastily decorated interior. Plans are now being prepared by the above firm for stained glass windows to adorn the aisles and chancel windows, representing the rood of the Holy Cross. The highest spire, on Plessis street, rises to a height of 220 feet above the sidewalk. The presbytery adjoining the church, now in course of construction, is in the style of Francois II, and is also built of Montreal limestone and covered with slate. The interior will be finished in Columbia cedar and nicely decorated.

UNION STATION, TORONTO.—STRICKLAND & SYMONS, ARCHITECTS.

This new station, which is now being constructed by the Grand Trunk Railway Company for the joint use of that Company and the Canadian Pacific, will, when completed, be one of the most convenient and best arranged stations in Canada. There will be two large train sheds, one for the use of eastbound and the other for westbound trains, with three tracks through each shed. The platforms will have an average length of about 1,000 feet, and there will be ample room to accommodate as many as twelve trains, averaging eight cars each, at the same time.

The approach to the station from the city will be by means of an entrance from Front street, the level of which is sufficiently high above the rails to enable passengers to pass from the street over the tracks to any platform, by means of bridges, and without having to ascend any steps, the various platforms being accessible from the overhead rooms and bridges descending to them.

The passenger who is leaving by train enters the station at the main entrance on Front street, opening into a spacious and lofty entrance hall, fifty feet square and thirty-five feet in height, on one side of which are ranged the ticket offices, and upon the opposite side the baggage counter, across which he can claim his baggage, and have it checked for its destination. This entrance hall is being finished in red sandstone, imported from Scotland, and pressed brick work, the floor being laid in marble, the whole presenting an appearance equal in artistic elegance to that of the main waiting room of most of the large modern stations on the American continent.

Having taken his ticket and checked his baggage, the passenger will proceed through a handsome arcade, with shops on either side, where travellers' requisities can be purchased, or where he can pass any leisure time he may have before leaving, to advantage.

The arcade opens at its southern end into a magnificent waiting room, eighty feet square and forty-five feet high. The floor will be of marble, and the walls to a height of ten feet will be of the same material, highly polished; above that it will be finished in carved red sandstone and pressed brick, and lighted from upper story windows on all sides. There will be a colored glass dome in the centre of the ceiling. First-class waiting rooms, lavatories, and ladies' retiring rooms open from this room on the east, and a luxurious restaurant and smoking room on the west. At the south end of this waiting room the eastbound train shed is reached, and across it is being constructed a closed bridge, twenty-six feet in width, fitted up so that when required it will serve as an overflow waiting room. From this bridge access down to the platform is obtained by various convenient stairways, and still farther to the south across the westbound train shed; and this bridge open to the shed gives access by stairways to other platforms.

These platforms extend both east and west, and the bridges are as nearly as possible in the centre of their length, so that the distance from the stairways to the cars is made as short as possible, no matter where the train is standing. All the platforms are being laid with asphalt, and those which extend beyond the ends of the train sheds will be covered with umbrella roofs.

The exterior of the building, of which the principal front is on Front street, is being constructed of Credit Valley brown stone from Messrs. Carroll & Vick's quarries, and red brick, and will have a very handsome elevation. The lofty tower will form a noticeable feature in the landscape. The upper floors of this building will accommodate the general offices of the Grand Trunk and Canadian Pacific Railway Companies.

Mr. Edmund, Wragge as Chief Engineer, and representing the Grand Trunk and Canadian Pacific Railways, has the general supervision of the entire work, Messrs. Strickland & Symons, of Toronto, being the architects.

A practical paperhanger says that the best way of removing solid bronze or gold papers, through which water does not quickly penetrate is to apply two or more coats of very thin paste, then to use a paint burner, taking care to employ the latter cautiously, and following up immediately with a scraper. The burner will not set fire to the paper, as the paste and wet paper will not burn, but it is well to have a pail of water handy in case of need.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The next annual meeting of the above Association is announced to be held in this city on Thursday, Oct. 4th and 5th, inst., in the rooms of the Association, New York Life Building. The following is the programme of the proceedings :—

THURSDAY, OCT. 4TH— 10.00 a.m.—Annual meeting, election of officers and routine business in rooms of Association ; 5.30 p.m.—Read-of papers in same place ; 8.00 p.m.—Opening of exhibition of drawings and conversazione.

FRIDAY, OCT. 5TH.—1.30 p.m.—Visit to the Redpath Library, Erskine Church, Chapel of the Sacred Heart, Power House of the Montreal Street Railway.

A photographic group of the members of the Association resident in Montreal is being prepared by Messrr. Wm. Notman & Son for which forty-two signatures have been procured and which will be presented to the members resident in Quebec, at the annual meeting.

The Association will hold an exhibition of architectural drawings in connection with their annual meeting in the galleries of the Art Association, Phillips Square, from the 4th to the 11th day of October.

The Council of the Association are associated in the holding of this exhibition by the Art Association of Montreal, who have kindly granted the use of their gallery for the purpose, and have promised their assistance and co-operation in promoting the exhibition.

The drawings are to be pen and ink or colour perspectives or elevations of modern original designs or sketches in ink or colour of old work, and in all cases the drawings are to be suitably framed.

Drawings are to be addressed to the Art Association, Phillips Square, and delivered there not later than the 29th September, and removed immediately after the close of the exhibition, the delivery and removal to be at the expense of the exhibitor.

The Council will take every care of the drawings while in their custody but they will be unable to effect an insurance upon them or be liable for damages that may occur.

Messrs. J. Venne and A. T. Taylor have been appointed by the Association a committee in association with Messrs. Wm. Brymner and N. Bourrassa and one member appointed by the Art Association, to select and hang the drawings sent for exhibition.

It was resolved at a recent meeting of the Council that the members of the Council along with Messrs. J. W. Hopkins, V. Roy, A. Raza and A. F. Dunlop be a general committee to make arrangements for the exhibition and conversazione.

AMERICAN PUBLIC HEALTH ASSOCIATION.

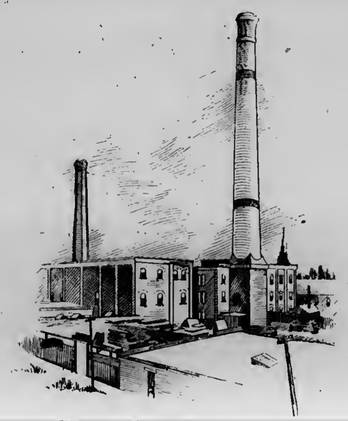
The above Association will assemble in annual convention in this city from the 25th to the 28th inst. The Association is representative of the United States, Canada, and Mexico. Dr. E. P. Lachapelle, of this city, has the honor of being President of the Association this year. A number of papers on sanitary and hygienic subjects will be presented at the approaching meeting.

THE CITY BUILDING BY-LAW.

In a recent issue, the Insurance and Finance Chronicle of this city published an article criticising the existing city building by-laws which it states are entirely inadequate for protection against fire. Although it must be recognized that our building by-law contains many defects, as the building inspector admitted when interviewed on the subject, they nevertheless possess many points that if observed would I think greatly add to the security of our flimsily built tenement houses and their contents. There are no set sizes as to dimensions of dwelling blocks it is true, but section 12 of by-law No. 107 passed in 1877 requires that when "rows or blocks of dwelling houses, stores or warehouses, are built, each tenement, store or warehouse shall be separated by a division wall of brick or stone, subject as to elevation and thickness to provisions of sections 11, 14, and 15 of this by-law," and moreover, section 11 therein referred to calls for the carrying of these fire walls over roof and for coping with incombustible material. If all buildings were built strictly in accordance with this by-law the block of tenements could no longer bear that name, but each tenement or store on its horizontal projection would be a distinctly separate and complete building, with no lateral communications whatever. Although architects are aware of the existence of this by-law, I saw a building recently going up on St. James street west, containing two stores on the ground floor with two tenements above ; these two tenements and stores were simply divided by a common wooden studding partition all the way up from cellar to roof. In that same building also, I noticed that instead of putting in a trimmer around the chimney for supporting the joists, the joists ran right into the chimney and came within five inches of the interior of the flue in spite of the by-law which distinctly forbids this. Numerous other infractions could be cited, amongst which may be stated the building of a single flue to a chimney used by more than one tenement or store, notwithstanding the by-law provides for a separate flue to each tenement or store. The latter infraction is almost of daily occurrence, responsibility for this conditions of affairs should be traced and a reform instituted. It is a well known fact that very often a building permit is only obtained when the building is almost completed. As to the thickness of brick walls, it is amply provided for in the table set forth in the said by-laws. A part of the present by-law which I think ought to be amended is the clause permitting the building of tenement blocks of wooden plank or frame, enclosed with brick. This section of the by-law says that such buildings shall not exceed two stories and a mansard roof in front, and three stories in rear, the highest point of the roof not exceeding 34 feet from the level of the foot-path. It is obvious that it is quite ineffective to have fire walls dividing each tenement if the exterior walls are allowed to be built of three inch plank. It is in this class of buildings that improvements should be made, and no buildings in the future should be allowed to be built of plank or frame. The Building Inspector has prepared a new by-law which is based on the existing building by-laws of the largest American cities, and which I hope will effect an improvement in the class of buildings heretofore put up in this city, and especially the poorer class inhabited by the working people. This by-law is now in the hands of a committee of the Province of Quebec Association of Architects, to whom it has been sent by the Fire Committee for suggestions. Let us hope to see it adopted and properly enforced at an early date.

NEW CHIMNEY AT TORONTO RAILWAY COMPANY'S POWER HOUSE.

WE present to our readers herewith an illustration of what is claimed to be the tallest chimney in Canada, its height being 250 feet. It has recently been completed at the power house of the Toronto Railway Company, under superintendence of Mr. James Hill, and was commenced during the early part of last March. Excavations were made to a depth of 18 feet, at which point solid rock was struck. The concrete foundation, 40 feet square, is built on the rock, and was tapered up till it stood 24



feet square at the surface of the ground, where the chimney proper was begun. For the first fifty feet the chimney is square, the top which is 18 feet 3 inches in diameter, being capped with cast iron. The inside diameter is 12 feet. A ladder made of U-shaped irons is provided as a means of ascending, the ends of the irons being anchored in brick. The smoke from a 10,000 horse-power of boilers can easily be carried by this chimney. An excellent view of the City of Toronto is afforded from its pinnacle.

In answer to an inquiry as to the treatment of the internal walls of a hospital ward, a correspondent to the British Medical journal says that of course a great deal depends on the material of which they are constructed ; but if they are plastered there can be but little doubt that a hard oil paint, or paint coated with varnish, forms the best finish, as it can easily be dusted or washed. As regards color that will depend to some extent on the amount of window space ; where there is plenty of light one can afford to make the walls of such a tone as to be restful to the eyes ; a very common defect in hospitals is making the walls too light. Ordinary hanging pictures are certainly inadmissable ; if they were properly dusted, which they never are, they would be knocked to pieces in three months. If pictures are desired, certain spaces should be reserved for the purpose, and the pictures should be pasted to the wall and varnished over. The same should be done with all tables of rules and regulations which one so often sees hanging on cards. They should all be pasted to the wall and varnished over, the object being that the wall and all upon it should be cleaned at one sweep.

THE BUILDINGS OF THE DOMINION.

BY G. F. STALKER.

UNDER this caption I wrote an article which appeared in the January number of the CANADIAN ARCHITECT AND BUILDER. The principal object of that paper was to advocate the advisability of establishing a system of competition for designs for our national buildings. It is satisfactory to know that the ideas expressed at that time have met with favor by some of our architects, and that there is a possibility of such action being taken as will bring about the desired change.

In the meantime the question has been taken up and definite proceedings instituted for the accomplishment of a similar object in the United States. In a recent number of the American Architect, and in the July issue of the Forum, articles appeared on the subject with reference to the buildings erected by the government of the United States. And, better still, on June 16th of the present year, a bill was introduced into the House of Representatives, "To provide for the securing of plans and for the erection of the public buildings of the United States."

I am not vain enough to imagine that the articles and the bill referred to are the result of my January paper ; but it is very gratifying to find oneself in such good company, and voicing opinions in keeping with the spirit of the times. The crusade which is going on everywhere against monopolies must, in the end, be successful. And success will be swift and certain when resolute action is taken in regard to the breaking down of restrictions that have been placed around an art which can boast of ages of liberty. The experiment has been tried, both on this continent and in Europe, of satisfying the architectural aspirations of nations by limiting the designs for national buildings to the skill of one man, and it has failed in every case. The causes of the failure have not been the same in each instance, but the result has been the same—failure. And if the present system is continued in Canada, we have before us the prospect of a continuance of architectural failures in our national buildings.

If the causes which have produced such unsatisfactory results can be ascertained, it may be suggested, a better era might be inaugurated by their removal, which would not necessitate an entire change of system. The writer of the article referred to in the Forum maintains that the causes of the failures in the United States are, mainly, the incapacity of the government architect ; and, in addition, the impossibility for any man to give sufficient time to the preparation of his designs, and at the same time attend to the routine work of what must, of course, be a large department of the public service.

With the first cause of failure in the United States, we, in Canada, are in no way concerned. No one can lay any such charge against our present government architect. It would, in fact, be almost an impertinence to place him in the same category with the majority of architects who have occupied similar positions in other countries. And, more than that, his special fitness for the position makes it a matter of the greatest delicacy for us in this country to agitate for a change of system.

But the second cause of failure is of universal application. More than one architect has resigned his position on account of it ; and every architect worthy of the name has found it almost impossible for him to give time and study to the proper and more congenial part of his work as architect, while keeping pace with his routine duties. And there is no way out of this difficulty. The mere multiplication of assistants and clerks will not overcome it, while it will materially increase the cost of working the department. So long as the one man system is maintained, the chief architect will find it necessary for him to give by far the greater portion of his time to routine business, a vast amount of necessary and important work of which the general public are profoundly ignorant ; while to or that portion of his duties of which the public take cognizance, and by his success in which, in their judgment, he has to stand or fall, he has to snatch a few odd hours from the worry and irritation of accounts and departmental cross-purposes.

When the designs for our national buildings are, of necessity, under the present system, produced in such an atmosphere, it is surely no great matter of wonder that there should be an imperative demand for a change ! If no other reason could be submitted than this, it would be sufficient to require it. For it must be evident that the object for which the system was instituted, namely, the retaining of the services of a great architect for designing our national edifices, is entirely frustrated by the conditions inseparably connected with such an office. We are, therefore, maintaining an expensive department in order that we may have a certain kind of work done in the best manner, but, from the very nature of the office, and the variety of necessary circumstances connected with it, we fail to obtain the accomplishment of its most important purpose.

Moreover, the establishment of the present system, some thirty years ago, was supposed and expected to be more economical than the ordinary method of securing the services of an architect. But experience has everywhere proved this also to be a fallacy. An examination into the matter proves, that, in the United States, what may be properly set down as architects' charges, in connection with the government buildings, amounts to about seven per centum ; and, in Canada, the charges exceed eight per centum. And this does not include, in either case, the cost of providing and maintaining office accommodation, fittings, lighting, drawing materials, &c., which would amount to about one per centum more.

We are, therefore, paying about eighty per centum more for architects' services, under the present system, than we should pay if the work were done in the ordinary way ; and, as we have seen, we incur this excessive expenditure for an inferior service. That is to say, for a building costing $1,000,000, the architect's charges would amount to $50,000, according to the usual scale, but the cost to the country for architect's services, according to the present system, would amount to $90,000.

But the greatest objection to the system lies in the fact that, by continuing it, we deprive ourselves of the opportunity of obtaining the best designs for our public buildings. This is at the bottom of the efforts now being made in the United States for a complete change of system. This brought about the change in England, and this has given rise to the desire in Canada—a desire which will, before long, develop into action—for a change in our system of securing plans, and of erecting our public buildings. And in the hope that measures will soon be adopted for carrying the purpose into effect in Canada, it may be of interest to consider the leading features of the bill now before the House of Representatives in the United States.

It provides for the appointment of a commission of public architecture, consisting of three architects, two engineers, and, as ex-officio members, the Secretary of the Treasury and the Supervising Architect of the Treasury, who shall procure designs and appoint architects for all buildings hereafter erected by the government. This commission shall select architects to submit designs in competition for all buildings costing $100,000 and over ; and they may appoint, without competition, an architect for buildings costing less than $100,000. The architects in every case must, of course, be well qualified men ; and, where a competition takes place, the successful competitor is appointed architect of the building on the usual terms, and the others receive an honorarium in proportion to the magnitude of the building. Power is vested in the commission for framing rules and regulations governing competitions, and the duties of the successful competitor are clearly set forth, and are in conformity with the usual professional practice.

Such is a brief outline of the American bill, and, with a few emendations, it would not be difficult to construct from it a measure that would be suitable to the exigencies of the Dominion of Canada. For we have seen that, in Canada, we have, as far as our national buildings are concerned, the same anomalies and the same failures as have occurred in the United States and in Europe. It surely cannot be said that we have less "sand" in us than the people of those countries, and that we are content to let things remain just as they are, though we know that the present system is pregnant with harm to our art, and discreditable to ourselves as Canadians ? And we are not so stupid as to imagine that any tinkering of the present system will ever produce any material improvement. We are satisfied that experience proves this to be a physical impossibility. Neither do we blame or disparage anyone who has held the office of government architect. But the experience of England and other countries places it beyond all question, that if we obtained the designs for our national buildings by competition, we would not only have better public buildings, but we would elevate the standard of architecture generally throughout the Dominion.

LONDON PUBLIC LIBRARY COMPETITION.

The information has been received that the competition recently held for designs for a public library building for the city of London, Ont., has at last been decided. A Mr. Matthews, a young student of architecture, formerly of London and Toronto, but now residing in New York, has been awarded first place in the competition, and will have the supervision of the work, which is to be commenced as soon as possible.

CANADIAN VS. FOREIGN CEMENT.

THE manufacturers of Canadian cement are protesting against the action of the Dominion Government in awarding a contract to a Montreal firm for 11,000 barrels of Belgian cement, in the face of the fact that cement of the best quality is now manufactured in Canada, and that the most of the Canadian cement works are at present shut down for want of orders. It is further pointed out that the stave mills in western Ontario are also closed down in consequence of the inactivity among the cement manufacturers who are purchasers of a large part of their product.

The protest of the cement manufacturers seems a reasonable one. Recent tests of the cement used in making concrete pavements in the City of Toronto, showed the cement made in Canada to be as durable, if not more so, than the foreign material. In view of this what necessity is there for the government engineers to pass by our home manufacturers. Mr. A. Blue, of the Ontario Department of Mines, in a paper read a few days ago before the Mining Association, made the surprising statement that of the 150,000 barrels of cement used in making concrete for street construction in Toronto, only 4,000 barrels had been native cement. There was, he urged, no reason why we should have to go abroad for Portland cement, as in Ontario we had an abundance of raw material for producing it.

REMARKS ON ESTIMATING.

As wooden buildings, either frame, balloon or plank, are mostly in vogue in rural districts, the country builder has more to do with them than with any other style of structure, so I will take as my model an ordinary balloon frame house in the country, and which is supposed to cost anywhere between $800 and $3,000, though the method of estimating I am about to formulate will hold good for buildings costing more or less than the sums named.

We suppose the plans, elevation, details and specifications of a building are now before the estimator, and on which he is now figuring.

In making out a "tickler," the estimator should use legal cap paper, using at first only every other line to make his list, as his first attempt will leave many omissions, which, as discovered, may be inserted on the blank lines under their proper heading. Having the paper ready, and any notes you may have prepared, head the first page "Preliminary," under which head may be written :

Preparing grounds and staking out building (giving supposed cost of every item.) ..... $....
Laying out and grading for drains, &c. ..... $....
Miscellaneous expenses in securing contract, ... $....

The next heading should be

MASON AND BRICKLAYER WORK.

— yards excavating ..... $....
Carting and levelling ..... $....
— cords of stone in foundation walls at — per cord .... $....
Brick walls, piers and chimneys ..... $....
Cellar floor, concrete or brick ..... $....
Cesspool and drainage ..... $....
Laying tiles in hearth ..... $....
Building fire-places and putting in grates ..... $....
Work and material around heater ..... $....

CARPENTER WORK.

— ft. in side, end and middle sills at — ..... $....
— ft. in trimming, posts and plates at — ..... $....
— ft. in main, side and end tie girths ..... $....
— ft. in first floor joists at — ..... $....
— ft. in second floor joists at — ..... $....
— ft. in ceiling joists ..... $....
— ft. of studding in outside walls ..... $....
— ft. of studding in gables ..... $....
— ft. of studding in inside partitions ..... $....
— ft. of studding in braces and for doors and windows .. $....
— ft. of studding in common rafters ..... $....
— ft. of hip, valley and jack rafters ..... $....
— ft. of trusses, purlins and collar beams ..... $....
— ft. of outside sheeting ..... $....
— ft. of inside sheeting ..... $....
— ft. of roof sheeting ..... $....
— ft. of gutter, lookouts, etc ..... $....
— ft. of floor lining ..... $....
— ft. of shiplap sheeting ..... $....
— M.M. of dimension shingles at — ..... $....
— ft. of siding (whatever kind) at — ..... $....
— ft. of battens, lattice, &c., at — ..... $....
— ft. of furring and bridging at — ..... $....
— ft. of fencing boards at ..... $....
Fence posts (state number) at ..... $....
Tarred or straw paper ..... $....

To all these items add cost of labor in working and putting in place. Keep account of labor on separate sheets, preserving all for future reference.

M.M. of four ft. lath at — ..... $....
— bbls. of lime at — ..... $....
— loads of sand at — ..... $....
— bbls. of plaster paris at — ..... $....
Water service (if any) ..... $....
— lbs. of shingle nails at — ..... $....
— bush. of cow or goat hair ..... $....

Add coloring matter if such is wanted for interior work or for rough-casting, also cost of pebble gravel.

Follow up this method of itemizing everything that will be used in the construction of the building, from the footings of foundation to coping of chimney top, each class under its own heading. Under "Hardware" place number, description and price of locks ; if more than one kind give each a separate entry. The same with bolts, hangers, furniture, window locks, screws, wardrobe hooks, pulls, grates, brackets, sinks, and everything else in this department.

Under "Plumbing" enter price, description and quantity of piping required, taps, traps, closets, bowls, drains, ventilators, bath tubs, hot water boilers, and all other plumbing requisites with the cost thereof.

Under "Joiners' Work," itemize everything that is to be finished in wood, classifying and describing everything, and giving price per piece or per foot, marking on margin of your paper a rough sketch of moulding, base, rail, baluster, or whatever else it may be. Do the same with any extra sash, doors or ornamental panels or newels. This precaution will serve you in future, and be handy to refer to on many occasions. Mantels, grilles and such like work may be entered in bulk, numbering the style of mantel or grille so that no mistake may occur. Stairs, with full description of riser, tread-strings and finish, may be entered at so much per step, or in bulk, either with or without rail and baluster and newels, making proper provision for landings or offsets. If paneled under soffit, make entry of same and fix price accordingly. Make special entries of labor required to lay down so many feet of this base, and so many feet of the other. Time fitting and hanging sashes, same for hanging and trimming doors, fitting up pantry, shelving and putting up hooks in closets, laying down floors, outside steps, posts, building veranadas, stoops or storm porches, cresting and putting up. Wood cornice—make diagram on margin, give dimensions and cost per foot. Wainscot, paneled ceilings, ornamental dados or fixed furniture, such as dressers, sideboards, cupboards, cabinets and hall racks, should be described and a sketch on the margin, with cost and style of finish. All other joiner work should be entered, with description and cost.

When any tinsmith or sheet metal work is required, a full account of it, giving amount and quality of materials used, with cost per foot, if conductors, leaders or gutters, and per square if for roofing or like purposes. Tin used in valleys or for flashings should be enumerated with full cost.

Next comes the painter, decorator and finisher. Enter quality of paints and oil, number of coats, colors and cost per yard ; style of finish, if on hardwood or stained pine ; number of coats of varnish ; state if rubbed and polished, with cost of same ; describe quality of glass, size, manner of glazing and cost per square. Itemize every particular and of every kind, teaming, carting away rubbish, cleaning up building, and everything where cost is attached.

Having now gone over the whole building, and itemized all that has suggested itself, go carefully over your work and look for omissions ; if any are discovered, enter them at once under their proper heads. Read over your specifications again and again ; examine the plans, elevations and details, until you are convinced you have grasped every detail, then go to work and copy into a convenient blank book, the results of your work, leaving a wide margin for sketches, and a line or two between each entry, and you have a "tickler," a complete and permanent "reminder" for all sorts of wooden buildings costing no more than $3000.

Your first [illegible] answers for an estimate of the particular building you figured on, and, if you find you have made any mistakes as to price of work, or cost and quantity of material, correct in your book so that you will not be misled the same way when estimating on another building.

It is usual in country places for the contractor to get the plasterer, the mason, the tinner, the plumber and the painter to give in an estimate on the work required of their various trades. This practice does very well, but it has the fault of throwing the whole responsibility of their work on the contractor without giving him a corresponding profit. It is better for the contractor to take the whole work, then he is master of the situation, and in a position to make reasonable terms with the other tradesmen.

If space permitted, I might give a column of current prices for building work of various kinds, that might be useful to the country builder, but just now that is impossible. At some future time, however, I may take the subject up.

A. Z. Z.

PERSONAL.

Three Toronto architects, Messrs. Webster, Bousfield and Woolnough, were called upon to serve on the grand jury at the recent assizes. This we take to be a recognition of the level-headedness of the profession.

The sudden death of Mr. C. F. Fraser, late Minister of Public Works for Ontario, which took place at the Legislative Buildings in Toronto last month, has occasioned wide-spread regret. It will be remembered that to the unsatisfactory condition of Mr. Fraser's health was due his recent retirement as head of the Public Works department, which position he occupied for twenty years. The new Legislative buildings were erected under his direction. The late Mr. Fraser was one of the ablest and most honorable of the public men of this country.

The death is announced at Ottawa, at the age of 74 years, of Mr. John Bowes, who for 40 years was employed in the Public Works Department in that city, and was superintending architect of the St. Vincent de Paul and Kingston penitentiaries, as well as the library of Parliament.

ESTIMATING THE VALUE OF BUILDING STONE.—In determining the value of any description of stone for building purposes the inadequacy of tests by chemical analysis is pointed out in a recent paper by a British architect, and, as concerns the more detailed examinations resorted to, the crushing strength, he states, is nearly always in excess of requirements, and is, therefore, to be considered relatively unimportant ; the absorption test, however, gives a fair indication of the power of a stone to resist frost, and in stones of the same class is also a criterion of the crushing strength, which appears to be higher the less the percentage of water absorbed. Still more satisfactory results are obtainable by subjecting the stone, while thoroughly moist, to a freezing temperature, repeating the operation several times, and ascertaining the weight lost from the block. Another inaccurate assumption mentioned is that the specific gravity of a stone is proportional to the strength ; and still another is the conclusion that the higher the proportion of silica the more durable the stone—the incorrectness of this latter assumption being manifest, inasmuch as it would involve the assertion that all sandstones are better than limestones, or even than granite.

DECORATION AND FURNITURE

CREOSOTE STAINS.

WHATEVER the origin of shingles may have been, it is certain, says A. Ashman Kelly in Painting and Decorating, that shingle staining is a modern American method of contributing to the external decorative appearance of residences and other buildings. That they fulfil that object there can be little doubt, even though it be true that the staining is not always satisfactory. Nothing of human origin ever is.

A recent writer calls attention to the practice prevalent in this country, of keeping rural houses glaring with fresh paint, instead of allowing them to become age-stained, as rural cottages of Europe are. Now, the stains we use are, in a measure, the equivalents of those produced by time on bare wood. Rare effects can be had by blending two shades together, and the single-tone stains are also beautiful and effective. There is no use denying their original beauty at least. People like them, and what people like they have, no matter what artisans may say against the object of their liking.

Creosote has for years been known as a most effectual wood-preservative. It was first introduced in England in 1858, and in America in 1865. It is extensively used in all parts of the world for this purpose. It is a product of coal tar, that wonderful and prolific source of so many useful and beautiful products. The distilling process gives us several grades of the article creosote, containing various hydro-carbons. The odor is unpleasant, pungent and strong, but soon disappears upon exposure to the fresh air. An idea of its remarkable penetrative power may easily be obtained by placing it upon a thin board. In a little while it may be detected upon the opposite side by its odor.

Thus may be seen that for an outside stain, a creosote preparation possesses peculiar value. Linseed oil is the vehicle employed to carry it, and the several beautiful shades given these stains, are obtained from ordinary painters' colors, ground in oil to the last degree of fineness. It is upon this point that transparency of colors hinges. Coarsely ground colors will not give clear translucent shades. This, I believe, is all the secret about the manufacture of creosote combination, but some of them are gas-stains, or are made from petroleum oils, and are not by any means to be recommended. It is difficult, if not impossible, to get lead paint to remain over such stains, or to keep the stain from striking through the lead coat. True, shellac varnish, that universal panacea for all painters' difficulties, good for a cut finger or a damp wall, may be used over the stain to prevent trouble, but the operation is costly, and prevention is much better.

The question of durability having been raised, it is worth while to enquire into this objection. Obviously, being in part creosote, a very lasting matter, creosote stain, coosidered solely from this point of view, is durable. But as to holding its color, that is another question. Probably it does it no better than ordinary paint. Some think not so well. A well known manufacturer of such stains declares that he has known of its retaining its original color for nine years, and he adds that it usually wears well from four to seven years. Much, however, seems to depend upon how the work is done. For instance, wet or green shingles are inimical to good wearing, just as with paint. This same gentleman tells of seeing a painter dipping shingles, one side of which were coated with ice. Where shingles are tied up in bundles, it would be well to untie them, and spread them out to dry, before dipping them. It is not unfrequently the practice, too, to employ cheap labor, such as boys or unskilled men, to do the dipping, and good results must not be expected where such is the practice. A quarter of a century's experience has taught me that it takes a skilled mechanic to sandpaper or putty well ; its not a boy's or laborer's work. Neither is shingle staining, simple though the work seems. Mr. Coppins tells us that he "has seen dry-rot in both stained and painted shingles." This could not possibly occur where thorough work has been done.

There was quite a hue and cry against creosote stains in the city of Buffalo, some time ago, and inquiry elicited the fact that some painters there, of prominence, I understand, had been in the habit of changing the original stains by adulteration, and in one or two cases (I forget which) one manufacturer brought suit, wherea shop made mixture had been substituted for the goods called for by the architect's specifications. This lead the New York Association to discuss creosote stains and staining, at one of their sessions, and Mr. Cabot, the well-known manufacturer, was invited to prepare and read a paper, which he did. Since that I have heard nothing concerning this matter.

Finally, as to the durability of creosote stains, it may be said that careful treatment is sure to render the most satisfactory results possible. The wood to be treated should be thoroughly dry. The stain should be keep stirred, so as to yield uniform color and density of material, and only linseed oil used to thin with. The boy or day laborer forgets to stir the stuff, and the boss puts in coal oil or turpentine. I never yet found a journeyman who did not object to using the creosote stains. It burned his hands or destroyed his eyes. It was poisonous. In part, these charges were true. Creosote hurts the eyes and the skin, but it is not poisonous. On the contrary, it possesses remarkable healing powers. It is efficacious on cuts, burns and sores, when other remedies fail. It at first causes some pain, but this soon passes away and healing begins. It is used to cure meat. Men who work in creosote stain works are healthy, and are never known to complain of the stuff injuring them in the least. They become accustomed to it. Painters would, too, if obliged to use it more frequently. A master painter, Mr. McInness, tell us that it burned his paint pots out. Salt, also would destroy his paint, and salt can hardly be said to be poisonous. Another objection to creosote stain is, that it vitiates water that is intended for curlinary uses. In any case where the water from a freshly painted roof is arranged to run into a cistern, allow the first few rains to run elsewhere, after which no trouble may be looked for. It would not poison a person who should drink such water, it would simply taste or smell unpleasantly. Where gas-tar or petroleum oil stains are used, it is likely that there would be trouble with the water as long as the stain lasted. A paint compound containing tar and petroleum and applied to a flat tin roof, I know to have vitiated the water ever after. Should the creosote stains contain poisonous pigments, such as the chromates of lead, their use would be objectionable on roofs intended to catch water for cisterns. Those stains only should be used that owe their coloring to non-poisonous pigments, such as ochres.

HOUSE DECORATION.

IN the concluding portion of "Studies in Design," Dr. Dresser gives the following wholesome advice to house decorators. The progress of the decorative art rests largely with ourselves. I now speak to decorators. If we make our works worthy of patronage, I believe that patronage will be bestowed upon them. I am often perfectly amazed at the conduct of decorators when they are requested to commence the ornamentation of a room, and can only explain their mode of action by assuming their utter ignorance of the art which they profess to practice. They, upon seeing their client, ask how the room is to be treated. "Do you," they say, "wish a wall paper?" "Shall it be a gold wall paper?" "Do you wish the room light or dark?" "I will send you up a number of papers to choose from, and you can select which you please!" Such utterances can only spring from gross ignorance or a foolish timidity. What should we think if, when a medical man is called to see us, he asked how we would like the complaint treated : what medicine we desire ; and if a tonic, whether we would have bark or arsenic? The decoration of a room is as much bound by laws and by knowledge as the treatment of a disease. A surgeon would not cut off an arm simply because a patient asked him to do so ; he would first ascertain whether it was curable. I have no knowledge of the treatment of diseases ; hence I commit myself to the care of a physician. I have no understanding of law ; hence I employ a solicitor. I am called in to decorate a room ; the client is as ignorant of my art as I am of his. Is it not my duty, then, to tell him that the room will look well if treated in such a way, or that its walls might be of such a color? If we have understanding of our art, it is easy to convince others, who are ignorant, that we have more knowledge of the subject than they have ; but we must be able to show a reason for the suggestions we make. Let it ever be borne in mind that every successful work executed by man is an advertisement of his knowledge and skill, and as such tends to ennoble or exalt him ; and that every work that he does which is offensive, untrue, or degrading —no matter who has dictated it—tends to his debasement, and is an advertisement of what can only be censured and should be avoided. I look to decorators becoming the great teachers of art in the country. If we, as ornamentists, get knowledge, and explain to our clients why we purpose treating their rooms in a particular manner, they will readily consent to the production of artistic rooms ; and when once they have lived in an artistic house, they will never again like the white ceiling and merely papered walls, for their tastes will have improved. Let us do all we can to exert an influence such as shall conduce to the rapid advancement of art amongst us. Let us make our decorations as durable as possible, for that which often wants renewing will never grow in favor. A decorated ceiling will last clean much longer than one that is white ; it is, then, an economy to have such. Honest work, which is the expression of knowledge, when associated with the gentlemanly bearing of the decorator, and gentle persuasion, will accomplish all we seek to achieve.

PUBLICATIONS.

The Review of Reviews for September gives surveys of recent Congressional and State legislation in special articles ; the comparative table of tariff rates, especially, will be found useful for reference purposes, as it shows at a glance all the important changes made by the enactment of the new law.

Mr. Fred T. Hodgson, architect, Collingwood, Ont., has compiled and published a useful handbook entitled "The Hardwood Finisher," which contains upwards of 90 pages of rules and directions for finishing in natural colors and in antique our domestic woods, and also miscellaneous rules for dyeing, gilding and bronzing. Copies of the book may be obtained from the author.

STUDENTS' DEPARTMENT.

SOME ASPECTS OF THE MUTUAL RELATIONSHIP OF ARCHITECTS.

We reprint in part the remarks on the above subject delivered by Mr. Macoicax Anderson in his presidential address to the students of the Royal Institute of British Architects, as follows :

You may be called on to aid by your testimony as experts in influencing judgment for or against your contemporaries. It has ever been—and I suppose it ever will be—the case that men will differ. Even the highest code of morality anticipated this in the qualified injunction. "If it be possible, as much as lieth in you, live peaceably with all men." No doubt there are some to whom the injunction does not apply, inasmuch as to live at peace with anyone seems to be with them a sheer impossibility ; but even with those who are peaceably disposed, circumstances will occasionally arise involving a principle which they cannot concede, and which render it necessary to appeal to the help of others either in law or arbitration. I cannot claim to speak on this subject as an expert, my appearance in Courts of law having happily—although unfortunately, too—been restricted to the discharge of the wearisome duties of a juryman ; but it has sometimes vexed me to hear some of my professional brethern, whom I knew to be men of probity, censured by others for appearing as witnesses and giving testimony against them. Such experiences, which are by no means restricted to the profession of architects, may be thought to be unedifying, and I confess that I regard the relationship as perhaps the least desirable and the most inartistic which an architect can occupy ; but yet I fail to see why the witness should be the subject of censure more than he against whom he testifieth. Is it not the fact that the last named is frequently the original sinner? How can light be thrown on a purely technical point other than by the evidence of experts ; and how can such evidence be obtained if none will appear as witnesses? How can questionable or derogatory proceedings be exposed if reputable men will not come forward to testify against them? Further, why should it be thought strange that men of the same craft should differ in the witness-box, so long as it is a patent fact that in scarcely any topic of ordinary conversation in society will the same view be taken? In this relationship the rule of guidance appears to me to be clear and simple. Do not consent to give evidence as to the works or character of a brother architect unless you are perfectly sure that you can testify from the safe basis of experience, and in the honest belief that what you testify is truth.

No dissertation on the relationship in which professional men stand to each other would be complete without some reference to the subject of professional etiquette. We have heard etiquette condemned. We have been told of the triumph of perjudice and jealousy to the detriment of the welfare of client or patient. We have even heard whispers of the neglect of patients rather than the consultation with the rival practitioner which might have saved life. Such rumors—if, indeed, they are true—are at best but exaggerated indications of exceptions which prove the rule. Etiquette gives honor where honor is due ; it rightly exposes impostors. Etiquette appreciates ability and encourages merit ; it scathingly condemns the individual and the society that live on borrowed plumes, assuming virtue if they have it not. Etiquette generously extends the arm of sympathy ; it would rather cut off the right hand than by word or deed injure others for the sake of personal aggrandisement. Etiqutte recognises all honorable methods of advancement ; it rightly looks askance at questionable expedients of self-advertisement, such as are too frequently resorted to. In a word, etiquette is the standard which unerringly gauges the reputation of professional men. Above the level of the gauge is to be found all that is honorable and commendable ; beneath it is all that is grovelling and unworthy. In the Harveian oration delivered at the Royal College of Physicians last October by Dr. Pye Smith, this subject was so happily delineated that I cannot refrain from quoting the words of the Harveian orator :—"Professional etiquete really means the observance of those rules which distinguish a profession from a trade, which makes our callings honorable as well as honest, which check the art of advertisement and direct our ambition to obtaining the suffrages—not of the public which cannot—but of our profession which can—judge truly, rules of conduct which are, in fact, nothing but the carrying into daily practice of the golden rule, to do to others as we would they should do to us."

PLASTER CORNICES.

Cornices are either plain or ornamented. In order to execute a cornice according to a given design, it is necessary to prepare a mould of several members, which mould is usually made of sheet brass, iron or steel, indented so as to represent exactly the forms and projections of the said members, and fixed into a wooden handle previously described. If the protection of the cornice exceeds 10 in., it is requisite to fix up wooden bracketing to sustain the same. This consists of pieces of wood fastened to the wall on which the cornice is to be formed, about 1 ft. apart, to which laths are to be nailed ; the whole is then covered with a rough coat of mortar, allowance being made for the thickness of the stuff necessary to form a cornice, for which about 1½ in. is generally sufficient. To run a cornice properly two workmen are necessary, who must be provided with a pail or tub of set or putty, and a quantity of plaster of Paris. Previous to using the mould they gauge a straight line or screed on the wall and ceiling, formed of putty and plaster, and extending so far on each as to answer to the top and bottom of the cornice to be formed. On the screed thus formed on the walls, one or two slight pine straight-edges are nailed, and a notch or chase being likewise cut in the mould, forms a guide to run upon. When all is so far ready the putty is to be mixed with about one-third of plaster of Paris, and rendered of a semi-fluid consistency by the addition of clean water. One of the workmen then takes two or three trowels full of the prepared putty on his hawk, which he holds in one hand, whilst with the other he spreads the stuff on the parts where the cornice is to be worked, the workman occasionally applying the mould, to see where more or less of the material is required. When a sufficient quantity has been put on to fill up all the parts of the mould, the mould is worked backwards and forwards, being at the same time held firmly to the ceiling and wall, by which means the superfluous material is removed, and the contour of the cornice completed to the form required. Sometimes it is necessary to repeat this operation several times, in order to fill up such parts as are deficient in the former application.

CEREMONIES ATTENDING THE LAYING OF FOUNDATION STONES.

Among the papers read at a recent Congress of Anthropologists at Berlin, was one referring to the above subject. "The mason's ways are a type of existence," said Goethe, and it was shown by Herr Rowald how from the earliest ages his work was started with due reverence, as if it united time with eternity ; the site consequently assumed more importance than an ordinary spot on the earth's surface. A king of Babylon considered it was worthy of record that he restored a pyramid on the original foundations. To this day what is believed to be the foundation-stone of Solomon's temple imparts a sort of sanctity to a mosque. The Capitol in Rome was four times erected on one site. For two thousand years there has been a temple on the site where Cologne Cathedral stands. Auspicious days were selected for laying foundation-stones, and a survival of the old custom still exists in Hanover, for a builder hesitates about starting a new building on a Monday. As far back as the times of the Assyrians the foundation-stones were accompanied by records, which were sometimes placed in cylinders of clay. From the interest attached to the stones it is no wonder that it became a custom to employ more than one. In Eastern ruins four have been found in positions corresponding with the cardinal points, and in the Bible angle or corner-stones and foundation-stones appear to be synonymous. In some Mediæval buildings twelve were laid, probably in honour of the Apostles. Money and precious stones were liberally employed as offerings, but in some parts of Asia and Africa it was not unusual to offer human sacrifices. In Siam a case of the kind occurred recently, and the custom was common when beginning Buddhist monasteries.

USEFUL HINTS.

Sandpaper is at present made with powdered glass instead sand. Glass is readily pulverized by heating it red hot and throwing it into water, and finishing the powdering in an iron mortar. By the use of sieves of different sizes of mesh, the powder can be separated into two various grades, from the finest dust to very coarse, and these should be kept separate. A strong paper is tacked down and covered with powdered glass of the desired fineness ; when the glue is dry the surplus glass is shaken or brushed off. Muslin is better than paper, and lasts much longer.—Woodworker.

One boiler horse-power or its equivalent every hour will in general heat the amount of space given below in the different kinds of dwellings :—Brick dwellings in blocks, as in cities, 20,000 cubic feet ; brick stores in blocks, 15,000 cubic feet ; brick dwellings exposed all round, 15,000 cubic feet ; brick mills, shops, factories, &c., 10,000 cubic feet ; wooden dwellings exposed, 10,000 cubic feet ; foundries and wooden shops, 8,000 cubic feet ; exhibition buildings, largely glass, 5,000 cubic feet. The above table will answer in general for estimating, although men who figure very closely go into calculations in regard to the actual amount of cooling surface which the building has for the sake of being on the safe side.

Moisture and Masonry.—Water is the most destructive agent to construction. There is no quantity so small which, if repeated, is not ultimately fatal. The softest as well as the hardest material must yield to its insidious attack. No adage more true than "Gutta cava lapidem." Our forefathers knew the connection between moisture and decay in soft material. Hence in the buildings of the districts where the soft stones prevail, the bottom courses of the walls will frequently be found to be formed of a hard and impervious stone, the strata of which are called by the quarrymen foundation-stone. Walls always above or always below water may, under certain cirdumstances, be laid without mortar. When between wind and water they never should.

USEFUL OFFICE BREVITIES.

In all levers the power is in proportion to the length of the arm on which it acts, which means that if the fulcrum is close to the body to be moved, the effect is greater than if it were nearer the balancing point or centre where the lifting force would only equal the downward pressure, increasing or decreasing as the fulcrum recedes or approaches it.

All plumb lines drawn to the earth's surface continue to its centre, showing that walls and other parallel erections are not in reality parallel, and if continued to a sufficient height a difference would be perceptible in the distance between them.

The same rule applies to horizontal lines, owing to the earth's curvature, which is 8 in. to the mile, making all lines drawn parallel to its surface similarly curved.

In making patterns for iron castings the iron in pounds is equal to the same weight of pine in ounces. A hollow cast-iron column is capable of bearing as much strain as a solid cast column of the same diameter.

To space any number of articles the thickness of same being given : Place them closely together and measure their combined width, then subtract this dimension from length of distance to be spaced, and divide the number of articles in the remainder.

A simple way to strike lancet Gothic arches is to join the apex and a point of springing, bisect this line, and draw a line at right angles to it. The intersection of this line with the springing line is the radius point.

To find mitres on the Steel Square.

12 × 12 = Square Mitre.
7 × 4 = Triangle.
13⅛ × 10 = Pentagon.
4 × 7 = Hexagon.
12⅛ × 6 = Heptagon.
18 × 7⅛ or 7 × 17 = Octagon.
22½ × 9 = Nonagon.
9⅛ × 3 = Decagon.

Half an ounce of iron loses one-eighth of its weight in water. A mans daily labor could be performed by 4lb. of coal.

Figures on the square for top and bottom cuts on common rafters :—

⅛ pitch	=	3″ rise	12″ run.
⅙ "	=	4″ "	12″ "
1-5 "	=	4⅘″ "	12″ "
¼ "	=	6″ "	12″ "
⅓ "	=	8″ "	12″ "
½ "	=	12″ "	12″ "
⅔ "	=	16″ "	12″ "
Gothic "	=	21″ "	12″ "

For hips substitute 17in. run for 12ft. run.

When a beam is fixed at one end the strain on it is four times as great than if it were fixed at both ends.

To calculate the area of an ellipsoid or spheroid : Call the base 10ft. and the height 7ft. Then $10^2 \times (7 \times 4) = 296$ sum of square of base and four times square of height $296 \div 2 = 148$ and $\sqrt{148} = 12.1655$ square 100t of 148. Then $12.1655 \times 3.1416 \times \frac{11}{28} = 191.09957$. Square feet and area of spheroid or ellipsoid.

Table of the gravity of wood from cork to lignum vitae :—

	Specific gravity.
Cork	246
Poplar	383
Larch	544
Elm and English fir	556
Mahogany, Honduras	560
Willow	585
Cedar	596
Pitch pine	660
Pear tree	661
Walnut	671
Fir, forest	694
Beech	696
Cherry tree	715
Teak	745
Maple and Riga fir	750
Ash and Dantzic oak	760
Yew, Dutch	798
Apple tree	793
Alder	800
Yew, Spanish	807
Mahogany, Spanish	855
Oak, American	872
Boxwood, French	912
Logwood	913
Oak, English	970
Oak, English, sixty years cut	1170
Ebony	1331
Lignum vitae	1333

To find out how many feet there are in one ton of mahogany :

1 ton = 20cwt. = 35,840 ounces in a ton.

Look to mahogany, and opposite you will find 560, which divided into the ounces in a ton, will stand thus :—

560)35840 = 64 cubic feet. Ans.

To find the weight of a body from its bulk :—

Rule.—Cubic feet × specific gravity = weight in ounces.

To find weight of a log of larch 14ft. long, 2½ft. broad, and 1¼ft. thick :—

2.5ft. × 1.25ft. × 14ft. = 43.750 ; then,
43.750 × 544 = 23800 ounces =
13cwt. 1qr. 3lb. 8oz. Ans.

The standard of specific gravity of bodies is water, one cubic foot weighing 1,000 ounces.

"GEOMETRICAL DECORATED" WINDOWS.

The important subject of the due subordination of the mouldings of Decorated windows was very ably worked out by Edmund Sharpe, though at the present day, when Gothic principles are so well understood, some of his comments may appear to give almost elementary information. He remarks on page 51 that "the different orders of the window arch seldom consist of the same mouldings, and do not often even resemble each other. This is, perhaps, less the case with the earliest windows than with the later ones." He proceeds to say, "On the other hand, the rich series of curvilinear arch-mouldings, commencing with Carlisle and ending with Beverley, exhibit profiles of great variety and beauty". Further on, "As soon, however, as the double ogee began to be a prevalent curve, the practice of repetition in the orders of mouldings, both of windows and doorways, became again very common." All this is very interesting. In some thirteenth century work there is good reason for saying the mouldings have the effect of bundles of reeds tied together, and this complaint is justified by their sameness, also by the want of proper prominence and boldness to the leading members of the several groups of mouldings. Again, page 53, Sharpe says, "The section of a tracery bar is usually the same on both sides. This rule, which may be said to obtain throughout the whole of the curvilinear period, has its exceptions in the Geometrical period. Occassionally the circular centrepiece has a different series of mouldings on the inside and on the outside. . . . Where, also, two orders of Foliation are used, not occurring together, a tracery bar will sometimes show a different profile on its two sides." Even were there no Mediæval precedent for what Sharpe has described, there can be no reason whatever why, when the architect thinks fit, he may not act according to the particular circumstances. For example, the employment of what has sometimes been called "edge-tracery" (*i.e.* where the fillet is dispensed with the plain chamfers or hollow chamfers, as the case may be, meet in an arris) is very useful where the tracery requires to be lightened, more particularly in wood-work. For the same mouldings can be used in the same window with or without the fillet. What is somewhat unfortunately termed a "false" mitre is also handy in those parts of tracery where the plan just mentioned does not suit, so as to get a perforation. Even although an architect gives a drawing of the tracery half or full size, he is sure to find that he can improve it when he has seen the masons set it out full size on the boards, as every architect ought to make a point of doing if he possibly can. It is very apparent that much of old Geometrical tracery was never struck in by compasses, and varies in outline where, according to rule it ought to be the same. In modern practice such a procedure is undesirable, but at the same time it will be found that an occasional deviation from compasses is a decided help. It was just remarked that some license might be taken in lightening tracery, but, on the other hand, there is occasionally an advantage in giving, at any rate, an appearance of strength where desirable by refraining to pierce according to routine. What ought to be avoided is any "cut-and-dried" look to a window. It should show the evidence of the care and thought bestowed upon it by the designer, and not look as if turned out from a mill. To make one last quotation from Edmund Sharpe :—"Much ingenuity is often shown in the manner in which these three members of a traceried window [*i.e.* window-arch, scoinson-arch and rear-vault] are respectively arranged and united with its lower part and with one another ; and the subject is one which deserves more attention and study than is usually bestowed upon it." These words might be written in letters of gold, so true are they. But, happily, since they were penned architects have begun to pay a good deal more attention to the point Sharpe alludes to than they did then. But, with the best intentions, what can the unfortunate architect do who is tied and bound by want of funds placed at his disposal? It is most difficult to find room for a window-arch well recessed from the exterior, an ornamental rear-vault, and a bold drop-arch for internal effect—for it means walls of substantial thickness. The successful treatment of a scoinson arch is important, for it gives a charming variety, and prevents a too large soffite where the window is placed at a considerable height. If treated in combination with an order of tracery distinct from that of the exterior of the window the effect is the more enhanced, as it gives that slight feeling of mystesy which is so valuable an aid to the architect.—Builders' Reporter.

Mr. Horwood, architect, recently from New York, has opened an office at 90 Bank Street, Ottawa.

It is understood that the Owen Sound Portland Cement Company, whose works were destroyed by fire recently, is being reorganized under the name of the Georgian Bay Cement Co., with a capital stock of $90,000.

MANUFACTURES AND MATERIALS

WIRE NAILS.

THE increasing use of wire nails to the exclusicn of cut nails cannot be explained says the Architect, Builder and Decorator, by the rules that commonly govern the substitution of one line of gonds for another which has had the field for so long as did the cut nails. It is no uncommon thing these days of advertising to see an old favorite driven from the market by a new and perhaps inferior article, through the judicious use of ink; while a really good article, well established in the esteem of the public, must be liberally advertised in order to hold its own. In this use of nails, however, no advertising seems to have been done, while what little investigation of the relative merits of the two kinds has been made, all seems to have given testimony in favor of the old style of nails. In spite of the fact that repeated tests have shown the cut nails to hold more than the wire nails of the same length and weight, and in spite of the weight of tradition on their side, which is usually of itself sufficient to hold the market for useful articles against any ordinary effort, the wire nails have pretty much driven the others out. Some dealers do not keep any considerable assortment of the cut nails, and others declare that they do not sell a fifth as many as of wire nails. It will not do to say that the favor shown by builders is all a mistake, and accept the testimony of the testing machines as altogether conclusive. There must be something upon which to found the very general belief prevalent among the people who use nails, that the wire nails are the better. Possibly the evidence of the retailer as to the relative condition of packing boxes put up with the two sorts of nails on their arrival at the end of their journey, may have weight. The difficulty the carpenter finds in pulling down his staging when built with the wire nails may be evidence to him of their staying powers. Whatever the cause, he thinks the wire nails will hold more than the others. When the wire nails were first generally introduced, they had only cut nails of the very poorest material to compete with, but that is not the case now, for there is no difficulty in getting cut nails that will clinch almost as well as the old "wrought" variety. In the larger size nails, the number to the pound of a given length is about the same, but in the sizes more commonly used there is a considerable difference in favor of the wire nails—enough to make them the cheaper at anything like the same rate per pound. The present popularity of the wire nails is such that the cut nails must be specified if one has any hopes of securing their use on buildings. That the cut nails of a given length are better for the general purposes of a building, there would seem to be no reasonable ground for doubting, being as they are, so much stronger when driven home. Nails are not expected to hold in a building after they are half pulled out. The "coated" or "cemented" wire nails would probably be of advantage in some building work, as although a more slender wire than the ordinary nails of the same length, their hold when driven home is allowed by all who have tested or used them to be phenomenal. So far as we have observed, they are, however, hardly known among builders. For such places as the lathing of an ordinary ceiling they would add greatly to the security.

A method of drawing designs on glass with an aluminium pencil has recently been brought out in France. This metal, like cobalt and some others, has the property of leaving a metallic trace, like that of a lead pencil, on glass quite free from grease, and the trace is so adherent as to be practically permanent if not removed by hydrochloric acid. The pencil employed has a rotary point, which is found to make the metal adhere better than a fixed point, as in the ordinary pencil.

HOW SLATE IS MINED.

The manner in which slate is mined and cut up for purposes to which it is applied is a process that is known to only a few people, because slate is not found in many places in this country, its principle source being in upper New England and Pennsylvania. It is not taken out of shafts but is quarried out of big holes in the earth.

The slate is blasted out in huge blocks, and is hoisted out by steam and turned over to the men who know how to reduce it to the proper size. Huge blocks of it are taken in hand by these workmen, who cut a niche into one end of each piece. Then they take a chisel and a mallet, and they are so skillful in directing their blows that they can split the blocks of slate in almost any way they please.

If you watch the slab on which one of them is working you will see a little hair line running through it, and presently the block will fall apart on either side of this mark. The workman will make this line straight through the middle or to either corner just as he likes. I do not know just how he does it, but he invariably accomplishes what he sets out to do.

The smaller pieces thus produced are taken in hand by another set of men, who split them up into sheets of the proper thickness for roofing slate. This they do with a long-bladed instrument about the shape of a putty knife, but many times larger, and if you saw them do it you would marvel how they got the sheets off without breaking them, and also how they could split them so thin. Some of these men can take a sheet of slate only one inch thick and split it thirty-two times. The usual number of divisions is sixteen. These sheets are taken and cut into squares by machinery.

Wherever there are slate quarries you will find a great many Welshmen, for the best slaters come from Wales. Boys follow the trade of their fathers, and there are whole families and settlements who know no other means of earning a living. —Exchange.

A size of shellac varnish would be useful on a fresh wall. Ordinary liquid wood filler is often used for this purpose. A coat of boiled oil is preferred by many painters for a size. But these oily surfaced sizes are hardly adapted for wallpaper, unless cut on surface with sandpaper. For water colours a varnished or painted wall is always an ideal wall, because of the absence of suction.

MORESQUE PLASTER DECORATION.

THE Moors employed plaster for the decoration of both the exterior and the interior of their structures, not only for the simple expression of form, but as a basis of polychromy. At Segovia there are several good specimens of exterior decoration, and it will not be out of place to particularize one. The front walls of the Alcazar are covered with a diaper in plaster with most artistic effect. Probably the work was wrought by means of a frame, either of metal or wood, in which the requisite pattern had been cut, as is done with stensils. This pattern was placed flat on the face of the plaster as it dried, and the pattern was cleverly incised, as it were, through the openings. It could also be pressed on the plaster until the surface pattern was impressed. The composition of the plaster for such purposes was doubtedly cared for, as well as the manipulation, for the durability of it has been tested by many centuries of exposure. A band of such ornament can be carried across brickwork, or round a brick-built tower, as it was by the Moorish artists. Examples of such application can be found in plenty, and it is always richly effective. The Moors showed fine judgment in the use of this ornamentation in relation to the whole building on which they applied it, not being led away by the facility they thus had for the employment of detail, but, using the work in uniform masses, or bands, they avoid any expression of pettiness by profuse and meaningless variety.

For the interior courts and chambers mural decorative work in plaster was of fine quality, and was cut and carved in situ by the artist; it was simply sculptured on the spot as stone or alabaster might be carved, no mould being used. The capitals of the columns were thus produced in delicately intricate work. At Toledo there is a synagogue that was constructed in the twelfth century by Moorish artists, and was afterwards forcibly seized and converted to Christian uses, where the application of plaster work of this kind is exemplified with conspicuous effect. The spandrels above the arches are all original carvings of arabesque pattern, showing delicate undercutting as well as surface work of peculiar beauty. In all parts of the structure there is that delightful variety in detail with unity of effect such as artistic handwork can give, but which mechanical repitition will not achieve. The mere play of light and shadow on such a carved surface, if it be white or of a uniform light tint, has a charm of its own; but when the carving is emphasized by colour the effect is most powerful. It is the principle of the work, not existing specimens of it, that we should copy; the same principles that we may see practically illustrated in the Alhambra, and equally in other Mahometan structures. We may not require the splendid harmonies of those wonderful walls for our purposes, but we should none the less learn from them to produce what we do want. We do want art in our plaster work. That plaster may be used truthfully and artistically we may learn from the

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2⅞ × 3	2⅞	131,000	15,188	
C	2 1/16 × 3	2⅞	130,000	14,751	
D	3 × 3	2⅞	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have a large quantity of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

CANADIAN ARCHITECT AND BUILDER.

VOL. VII.—NO. 10. OCTOBER, 1894 PRICE 20 CENTS $2.00 PER YEAR.

THE
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2259.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this Journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

RECENT tests at the School of Practical Science, Toronto, of samples of porous terra cotta brick of ordinary red brick size, for use as interior linings of brick and stone walls, are said to have demonstrated the fact that these bricks have an average ultimate crushing strength of 12 tons per foot, and that a 6-inch arching is sufficiently heavy for ordinary office building construction.

IN the present number is printed the first of a series of articles which will appear regularly in succeeding issues of the ARCHITECT AND BUILDER, over the nom de plume of "The Bystander." These articles will be written in the form of notes by a member of the staff of this Journal, and will treat of architectural and kindred matters of current interest. The publisher will appreciate any information which friends of the ARCHITECT AND BUILDER may place at "Bystander's" disposal, and which would assist him to give interest and value to his department.

IN our illustration pages will be found portraits of all but two or three of the officers of the British Columbia Institute of Architects. We regret our inability to include in this group portraits of *all* the officers of the Institute, owing to the failure of some to respond to repeated requests for photographs. After delaying publication for several months in the hope of being able to complete the group, we have been obliged to present it in the somewhat unsatisfactory form in which it appears in this number. Friday, the 2nd of November, has been fixed as the date on which the annual meeting of the Institute will be held in the City of New Westminster. We hope to be able to print in our November number an account of the proceedings.

THE citizens of Montreal are considering whether or not they will hold an Ice Carnival during the coming winter. To those who favor such a project we would say, don't do it. No doubt the festivities of these Carnivals are pleasing to many and attract a large number of visitors to the city, but the advertising usually done for the occasion is of a kind calculated to do Canada more harm than good. It is unfortunately true, that outside of this country the opinion of the majority of people is that we are entitled by climate to the exclusive use of all emblems suggestive of cold weather. This is not more true of Canada than of many other countries. In proof of this statement we can point to the variety of crops that are produced here, including all fruits grown outside of the tropics. There is a habit, altogether too prevalent among our people, of representing life in Canada, or thoughtlessly allowing it to be represented, as if the distinguishing characteristic of the climate were extreme cold with almost perpetual snow and ice. We are all familiar with such representations in many Canadian pictures. We wish to protest against such a setting for Canadian works of art, whether in print, on canvas or in more enduring forms, and would like to see our people and artists in every line co-operating to correct the wrong impressions, which, as stated, are already too widespread. Our aim should be to show Canada to the best possible advantage at every opportunity.

THE voters of Chicago are to decide next month whether or not they will erect a new City Hall and Court House at a cost of about five millions of dollars. It is proposed to remove the present Municipal and County buildings which were completed eighteen years ago at a cost of three and a half-million dollars or so, and rebuild on the same ground. All the world knows that Chicago has had a marvellous growth within the last eighteen years, but it is not for this reason alone that a new City Hall is wanted. The buildings to be removed have been undergoing repairs almost constantly since completion. The manner in which the Corporation is setting about the proposed new work is likely to result in another gigantic failure so far as securing the best possible design and economy in the expenditures are concerned. Advertisements are out for a farce competition which will probably secure one set of plans and one estimate, duplicates of plans which, it is understood, the committee in charge already have in their possession and intend to use. The great need in the erection of large public buildings here or anywhere else, is honest competition for architects and contractors, and no effort should be spared to bring about these conditions.

ONE of the principal features of the annual convention of the Province of Quebec Association of Architects this year, was the exhibition of architectural drawings in the galleries of the Montreal Art Association. We are pleased to notice that in addition to the large exhibit of the work of local architects, a considerable number of drawings were contributed by members of the Ontario Association of Architects. The exhibition was attended by a large number of leading citizens, and cannot fail to serve a useful purpose in arousing public interest in the work of the profession and in architectural matters generally. This is one of the objects which the O. A. A. at its last meeting proposed to attain by means of a series of public lectures. It might not be out of place for us to suggest to the O. A. A. the advisability of undertaking an enterprise similar to the one which has been so successfully carried out in Montreal. No doubt the authors of many of the drawings which were exhibited at Montreal, would consent to have them come to Toronto. It is several years since anything in the line of a public exhibition of architectural drawings was attempted here, and there consequently exists the better opportunity for a successful effort in this direction. Reverting to the Montreal meeting, it is to be regretted that there were not more papers, and that the opportunity for a profitable discussion on the two excellent papers presented by Messrs. Baillairgé and Taylor, was not taken advantage of.

A NEW organization was formed in New York last month to be known as "The Employers' and Builders' League." The purpose of its formation is that by careful, conservative action, the interests of owners, contractors and journeymen may be conserved; also that by arbitration and discussion all necessity for strikes, lock-outs, liens and disputes may be avoided. One provision in the constitution of the league in favor of workmen is as follows: "The directors may nominate, appoint and remove when expedient, four journeymen in each craft, who shall be representative conservative men, to be known as master stewards, and these men shall be the recognized medium of communication between the Board of Directors and the journeymen." The organization is purely defensive, with the object of securing fair play for employers and employees. Union or non-union men will all be treated alike. A strong provision in favor of employees is, that every man will have a guarantee from the organization that he will get his wages. The membership roll includes fifty eight employers and every branch of the building trades. We do not understand just why the objects sought for could not have been as well promoted by and through the New York Exchange of the National Builders' Association, but the fact that another organization was considered necessary by a large number of the most prominent New York builders convinces us that the field for its usefulness is plain and raises the question again, why should not Canadian contractors be more generally and thoroughly organized? It would be simply absurd to say that the conditions are so different with us that contractors do not need to work for each others' interests on the lines that are followed elsewhere. The conditions are not likely to be just the same in different large cities or in different parts of the country, more or less remote from each other, but as between Canada and the United States the situation will average very much alike. We firmly believe as much good can be accomplished in Canada for contractors and builders through better organization, as in any other country. It is not our purpose in this connection to set out in detail our reasons for this opinion. We have had occasion to refer to some of them in former issues and will probably do so again in the future. We would be glad to assist by all possible means in promoting a greater interest in this question among contractors, and should they provide a suitable opportunity, will endeavor to point out some methods which could be adopted with benefit to all parties interested.

THE statue of Sir John Macdonald, which was unveiled in the Queen's Park on Saturday, 15th inst., before an assemblage variously estimated at from 15,000 to 18,000 people, and with appropriate ceremonies and speech-making, is the work of Mr. Hamilton McCarthy, R. C. A., the well-known and talented Canadian sculptor. The site selected for the statue, directly opposite the Queen's ave., and in front of the Ontario Legislative Buildings, could hardly have been more prominent or favorable for a purpose of the kind. The criticism, indeed, has been made, that the position is so exceptional that it ought to have been held for a statue of Her Majesty. The work of the sculptor is spoken of in kindly and complimentary terms by those capable of judging of its artistic merits, and it is undoubtedly a marked advance on the statue of Egerton Ryerson, also from the hands of Mr. McCarthy. The statue itself, the work of a Canadian artist, so also is the pedestal entirely a Canadian production. The granite was quarried in the Province of Quebec and was shipped to this city in its rough state. The designing, cutting, polishing, and the whole of the work was done in this city by D. McIntosh & Sons. These unveiling ceremonies naturally suggest a reference to the excellent paper in another column, "Notes on Some Aspects of the City of the Future," by Mr. A. T. Taylor, and which was read before the Quebec Association of Architects at the meeting this month. The particular suggestion of this paper is that the time has arrived, when, in all our larger communities, there ought to be in existence a committee, which will constitute a special artistic authority or tribunal, who will decide in the matter of selection of our monuments, statues, and the embellishment generally of our streets, public squares, etc. Mr. Taylor pertinently remarks: "How intelligent men will consult lawyers on all legal questions, doctors on matters of health, engineers on matters of drainage, hydraulics and machinery, but on matters of art and taste think they are quite capable of judging for themselves". Such a committee, it is to be expected, would be composed of men who were experts in artistic pursuits Were a committee of this character in existence in many cities of Canada, as well as elsewhere, future generations would not be called upon to ask for an explanation why this manner of designing some public building, locating a citizens' park, or placing some statue or monument, had been done with so little regard to esthetic and artistic thought and observation. In how many cities are large amounts of money wasted in undoing, in the line of public work, what had been improperly done in the first place. In this respect the question has an economic bearing that must touch the pocket, even though the artistic organs, to employ the language of the phrenologist, have been but poorly developed. The suggestion, as Mr. Taylor has pointed out, is not chimerical, as a scheme of the kind is in operation in Boston, and New York has also a municipal art society "established with the express object of providing adequate sculptural and pictorial decorations for public buildings and parks." The argument is sometimes used that in the newer cities public affairs are conducted on too utilitarian a basis to permit of thought in artistic directions. Those in the newer cities, profiting by the experience of older communities, might well avoid the mistakes made in this manner, and if no other influence will move the people there is abundance of force, as has already been suggested, in the purely economic and financial bearings of the question.

Sandpiper is at present made with powdered glass instead of sand. Glass is readily pulverized by heating it red hot and throwing it into water, and finishing the powdering in an iron mortar.

MR. CHARLES BAILLAIRGÉ.

WE have pleasure in presenting to the readers of the ARCHITECT AND BUILDER the accompanying portrait of Mr. Charles Baillairgè, the newly-elected President of the Province of Quebec Association of Architects. Mr. Baillairgé was born in the city of Quebec, on the 27th of Sept., 1826, and received his early education at the Quebec Seminary. Subsequently he engaged in the study of surveying, architecture and engineering. Many of the principal churches and other public buildings in the city and province of Quebec were erected from his designs. In 1866 Mr. Baillairgé was appointed City Engineer of Quebec, a position which he still holds. He has found time in the midst of a life of unusual activity to contribute to the technical societies and the technical press of this and other countries a number of valuable papers on a variety of subjects. He is likewise the author of several books.

We are pleased to observe that Mr. Baillairgé is keeping in view the important subject of the proper education of the rising generation of architects, and we hope to see some definite action taken during his term of office in the direction of providing the means of imparting to students the knowledge without which they cannot properly rank as architects.

MEASURING AIR.

SPEAKING of the work of the Massachusetts State inspectors of public buildings, the Boston Journal of Commerce says that, in inspecting the means of ventilation in a school house, great care is taken by the inspectors to secure all the data for an accurate and intelligent report. The barometric pressure, temperature, and relative humidity of the outside air are first taken, together with the force and direction of the wind. The location of the building as to points of the compass, the position and direction of the fresh-air ducts, and location of the inlets and outlets in the rooms, are also noted. Upon entering the room to be examined, thermometers are placed in various positions, on the inlets and outlets, at the teacher's desk, at the breathing line and floor among the pupils, and near the outer door.

MR. CHAS. BAILLAIRGÉ.
President Province of Quebec Association of Architects.

Careful measurements are then made of the volume of air supplied to and removed from the room by the ventilating apparatus. These measurements are made by taking the velocity in feet per minute of the air at the inlet or outlet by a standard anemometer, and then multiplying this velocity by the average working area of the opening in square feet.

For example: The inlets and outlets are usually covered by wire gratings or by ordinary register facings, which obstruct, to some extent, the flow of air, and it is seldom the case that the air is found to be flowing alike through all parts of the opening.

Proper corrections being made for these variations, and for the running of the anemometer, a very close approximation to the actual volume of air passing through may be obtained.

After keeping the doors and windows of the room closed for one hour, a test is made to ascertain the amount of carbonic acid in the air, the amount of this gas present being considered as a fair index of the other and more dangerous impurities in the air of the school room.

This test, unless great accuracy is desired, is usually made with an instrument invented by Professor Wolpert, and called, for him, a Wolpert air-tester. This instrument is very simple, consisting only of a glass test tube, on the bottom of which is a black mark, an inner tube of glass, and a rubber bulb, all of a specified size, and a stand in which to hold the tube.

The test tube is filled to a certain height—marked on the tube—with lime water, and by means of the inner tube and bulb air from the room is passed through the water until, by the formation in it of carbonate of lime, the water is rendered so opaque that the black mark or spot cannot be seen.

A table, furnished by the inventor, shows by the number of times the bulk has been filled how many parts of carbonic there are in 10,000 parts of air.

There are various sources of error, both in the measurement of the volume of air and in determining the amount of carbonic acid, which have to be carefully guarded against by the inspector.

This has been so well done in testing the air that in a large number of tests made with a Wolpert tester at the same time that samples of air were taken for chemical analysis, the average difference between the amount given by analysis and by the Wolpert-test was only 67-100 of one part in 10,000.

Tests to show the circulation of the air through the room are also made, usually by means of gunpowder smoke.

The report of the inspector, when complete, gives, in addition to the outside conditions already noted, the volume and temperature of air supplied and removed, the temperature of the room, the relative humidity of the air, the amount of carbonic acid found in it, and the results of the tests for circulation.

For determining the barometric pressure, relative humidity, and temperature, and also for measuring the flow of air into and out of the room, the very best and most accurate instruments to be procured are furnished to the inspectors by the State.

These gentlemen by long practice and habits of close observation have become very expert in the use of the apparatus employed in testing air supplies to school houses and other buildings, and they are also equally expert in regard to methods and systems of heating and ventilation, their wide experience placing their knowledge and judgment in such matters far above those of men of limited experience in such matters, or mere theorists.

PERSONAL.

The death is announced of Mr. John E. Turnbull, Inspector of government Buildings, in the maritime provinces. Mr. Turnbull was a native of St. John, N. B., and lived in that locality the greater part of his life. He established the first planing mill in New Brunswick. He had reached the advanced age of 76 years.

The marriage is announced on the 18th September, at Rusholme Congregational church, Manchester, England, of Mr. J. C. B. Horwood, architect, Toronto, Ont., to Mary Ethel, eldest daughter of Mr. John Jones, Manchester. The CANADIAN ARCHITECT AND BUILDER would express the hope that, to Mr. Horwood and his bride the perspective of life may never appear less pleasing than at present.

In connection with the mention made in the ARCHITECT AND BUILDER for September of the materials which are being employed in the erection of the new Union Depot at Toronto, it should have been stated that Don Valley pressed bricks and terra cotta manufactured by Messrs. Taylor Bros., of Toronto, are being used in the building.

THE test of steam-pipe coverings, says Heating and Ventilating, leads to the conclusion that it costs $15.48 to run one hundred of naked two-inch pipe at from 70 to 80 pounds pressure for one year of 3,000 working hours, with coal at $2 per ton. With the least efficient of the coverings used in the test, this loss could be reduced to $4, with the most efficient to $2.64. Striking as are these figures they are probably below cost of actual practice, for steam pipe is under pressure usually more than ten hours a day, and $2 per ton is below the average cost of coal. Prof. Charles B. Gibson, in some tests made for the Manufacturers' Mutual Insurance Company some years since, reached the conclusion that with coal at $4 per ton and 3,000 working hours per year, the loss from a naked two-inch pipe was 6½ cents per linear foot, considerably more than Mr. Dickinson's test would show even with coal at $4 per ton. However, the lowest of the estimates shows the importance of covering the pipes and it is a good thing to attend to before the present loss is increased by the coming cold weather.

THE BYSTANDER.

THE interest manifested by Canadian architects in the suggestion to throw open to competition designs for our national buildings, shows that many among the profession have been thinking along the same lines as Mr. G. F. Stalker, of Ottawa, in his article in these columns last month. The Bystander has talked with a number of architects recently, and they have been, without exception, of one mind on this question. The only point on which any seemed desirous of being guarded in their expressions was in their references to the present government architect, of whom all spoke in the highest terms. On this point, it was clearly shown how the force of agitation for a desirable reform may sometimes be broken by the faithfulness and ability of a public official, just as agitation for some reforms have their inception in the incapacity of an officer, where, perhaps, the system itself may not be faulty. As President Burke, of the Ontario Association of Architects, said to the Bystander, "There is a wide difference between the gentleman at the head of this department of the public service in the Dominion, and Supervising Architect O'Rourke, of the Treasury Department of the United States." "But then," continued Mr. Burke, "the principle involved in the suggested change is the same, whether in Great Britain, the United States, or Canada. And loyalty to the most efficient public servant ought never to be allowed to stand in the way of attaining that which principle establishes as right, and experience has shown is wise. In Great Britain the practice of giving the profession generally an opportunity to exercise their talents in designing for public buildings has proven an undoubted gain to the mother land, financially, and also from a strictly professional point of view, in securing a better class of buildings in every respect."

× × × ×

Other architects with whom the Bystander talked were just as definite in their statements as the President of the Architects' Association. If the subject is to be discussed from a public standpoint, there can be little question that the change is imperatively needed, and no doubt this fact has had much to do in securing the passing of the United States bill, a very clear outline of which was given by Mr. Stalker in the article published in last month's ARCHITECT AND BUILDER. En passant, it may be remarked, that the estrangement of opinion between Secretary of The Treasury Carlisle and Supervising Architect O'Rourke has at last culminated in the head of the Treasury Department summarily removing Mr. O'Rourke, and the Architects' Bill, it may be generally conceded, has now, practically, become law. Mr. Glenn Brown, who entered into the question of architects' charges, exhaustively, in the American Architect and Building News of some few months since, comparing cost of construction of many buildings as under the supervision of the government architect, or when in private hands, has presented a case, which in point of financial cost, seems wholly unanswerable. The Bystander does not intend to burden his comments with any large quotation from Mr. Brown's article, but it is to be remarked, that when we find a building, erected under the supervision of a government architect, as was the case with the Custom House and Post Office at Albany, N. Y., costing $811,204, or 102.8c. per cubic ft. to construct, and requiring 11 years for completion, and we place alongside of this a building erected at Kansas City for the New York Life Insurance Co., the work under the supervision of a private architect, and this costing $950,265, or 38c. per cubic ft., and completed in two years, whatever may be the opinion among professional men, the conditions are of a character to set ordinary citizens thinking. This case is only one out of many cited by Mr. Brown in his carefully tabulated statement. Mr. Burke was asked, how so wide a difference in cost was to be explained. Was it a case of the government architect drawing a fat salary? "It is not here the trouble rests," said Mr. Burke. "In fact, compared with the responsibilities of the office and the class of work performed, Mr. O'Rourke was in receipt of a meagre salary. The trouble is in the amount of routine about the business—the curse too often of all public work. There is a whole regiment of employees, civil service officers, connected with the department, and they do their work in a perfunctory manner that is never known in business circles, but that is indigenous to officialdom. Here is where the cost comes in. Push and energy are unknown, and the work is allowed to drag along without much regard to the time actually consumed."

× × × ×

The strongest argument in favor of a change in system, as seen by architects, was the advantage to be gained in the character and style of the buildings to be erected, if thrown open to competition. "It matters little how competent may be the government architect," remarked Mr. Langley, "he is bound to get into a rut, when the work is left continuously in his hands from year to year." A similar thought was given expression to by Mr. Siddall, of Siddall & Baker. "No man," said he, "can give freshness to his work when he is burdened with all the details of management, as must be the case with anyone holding the position of government architect. There is a want of incentive for such an officer to keep in close touch with the advances that are being made in architectural and building lines. "The Bystander was reminded in this connection of a protest he had heard against uniformity in building in general, when this policy is pursued, as it sometimes has been pursued, by communities: "Never lapse into deadly dullness, the modern classic monotony of later Spain." Perhaps it is that arguments of some force can be advanced against any change in the present system, so far at least as Canada is concerned, but the Bystander has so far failed to learn of any of these as he has talked over the matter with those active in the profession. The strength of experience is always worth much, and the fact that the system of public competition has worked so admirably in the public interest in Great Britain, as well as having given strength and encouragement to all interested in architectural pursuits, is to many minds sufficient argument to influence the various Canadian architectural associations to take steps to secure legislation along the same lines. In doing this they would only be following in the circle, along with the mother land, and their neighbors to the south.

× × × ×

A short time since designs were asked for by the Free Library Board, of London, Ont., for the erection of a new building for library purposes in the Forest City. A statement of specifications and particulars was sent out to those architects who desired to compete, and about 20 architects, it is said, in different parts of the province, sent in designs. Within the past month the award was made and to the surprise of those who had adhered strictly, as they believed in honesty they ought to have done, to the requirements set forth in the specifications, they learned that the Free Library Board had accepted the plans of an architect in Brooklyn, N. Y., whose drawings, it is alleged, were not in accordance with the specifications. The party who has been successful in the competition was a former resident of London. It has been stated, now that his plans for the London building have been accepted, that he will return again to Canada. Just how far this is the case, however, the Bystander is not prepared to say, and whether any significance is to be attached to the fact that the award was given to an "Old London Boy" is a matter that the people will decide according to the various ways of measuring up a transaction of this character.

× × × ×

The interest of the Bystander was in ascertaining the feelings of the profession in a case of this kind. Messrs. Siddall & Baker, who were among the aggrieved parties, were seen, and both members of the firm were very indignant over the action of the London Board. They said a protest which they and others had signed, had been forwarded to the Board, but whether any good would come out of it time only would tell. In the opinion of Mr. Baker it ought to be the duty of every architect to protest against conduct of this kind. "What is the use," said he, "of asking for plans on certain lines, if others are to be permitted to deviate from these conditions and undertake to secure, perhaps a little more for their clients as a step to secure the award. A continuation of this practice must inevitably lead to corrupt and immoral methods in competing for work. We have enough of this kind of thing in other walks of life, and if the dignity and character of the architectural profession is to be maintained, we should act as one man, not alone, in denouncing conduct of the kind, but we should unanimously take steps to prevent, if possible, its recurrence in other ways." Mr. Beaumont Jarvis, who had also entered the competition, was spoken to about the matter. He had signed the protest that was being entered, and with Mr. Baker he agreed that the subject was one that might fairly enlist important consideration from the architects of the country.

× × × ×

The Bystander was amused by the rejoinder made to his enquiry by another well-known architect. This gentleman said: "I do not know anything about the London competition. Our firm certainly did not enter the competition, and have not been asked to sign any petition objecting to the award. But these people who have found themselves disappointed ought never to have entered the competition. They ought to have known better than to have expected anything like fair dealing in these competitions. We have long since refused to endeavor to secure business in this manner, having learned from our experience that the man who has the biggest pull on interested parties, or who has become an adept in wire pulling, is usually the one who 'gets there.' We are out of that kind of business." The argument was one, that seemed to give force to the contention of Mr. Siddall, that it was time for architects to unite in an effort to remedy so rank an evil. But when taking steps to remove the mote out of their neighbor's eye, what about the beam that may be in their own? The Bystander has had this question suggested to him through a remark made by a builder a few days ago: "I never think of tendering for work in the hands of Mr. So-and-So, naming a certain local architect, for my experience has been that his office is a close corporation, and tenders for buildings of which he has control never go outside of a certain favored circle." Surely it cannot be that the architects of Canada will allow themselves to be tainted in any way with the spirit, and indeed the practice, of corruption, that seems to float about the air these days as do the bacilli of so many diseases that attack the physical man.

× × × ×

The death on the 7th October, at his home, Beverley, Mass., of Oliver Wendell Holmes, the genial and clever author of the Autocrat of the Breakfast-Table, reminds one of a remark of the dead "Autocrat," when urging people who have information to impart of service to their fellowmen, "to set their thought-sprinklers to work." The Bystander in his journalistic experience has found it one of the hardest things possible to get men—ladies are excepted of course—to tell what they know to others. Every newspaper editor realizes how difficult it is to get men, well informed and with the ability to do the work, to put their pen to paper and to impart from out of their knowledge information of benefit to their fellowmen. It is sometimes almost as difficult to get some people to talk about what they know. They are as mum as an oyster, keeping their thoughts hermetically sealed. The Bystander has no brief from the editor of the CANADIAN ARCHITECT AND BUILDER to quietly probe this journal's readers and ask them to be a little more generous in their discussion of matters of interest to others in the same line of business, but he is quite sure, if the editor is like other editors, that he will appreciate the setting to work of the "thought-sprinklers" of his readers. The Bystander, as he meets with the architects and builders of the country from time to time, will be glad to have them turn the faucet on occasionally and keep him posted in what is uppermost in trade matters.

PUBLICATIONS.

The Rathbun Co., of Deseronto, are sending out a handsome catalogue relating to their porous terra cotta for fire-proofing purposes, with illustrations of the material and numerous public buildings in the erection of which it has been employed.

In the October number of the Engineering Magazine appears a new and very valuable feature in the form of a "Review of the Industrial Press," with an index to all the leading articles published currently in the technical Journals of the United States and Great Britain. The readers of the Magazine are not only made acquainted with the most important matter appearing each month in the technical Journals, but they can be supplied through the publishers with copies of any articles which they may desire to possess at a moderate cost.

It seems probable that a new City Hall for the City of Quebec will shortly be commenced. The Council has been authorized to issue debentures to the amount of $150,000 for carrying out the project. The site which will probably be chosen is the Jesuit Barracks Square.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

A CORRECTION.

OWEN SOUND, 1st October, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—We noticed in your September number an item referring to the Owen Sound Portland Cement Co., whose works were destroyed by fire, stating that the company is being re-organized under a new name. We wish to correct this statement, as there is no re-organization, or change in the company's name. We will still continue our business under the name of the Owen Sound Portland Cement Co., Limited. The cement works, which are situated at Shallow Lake, about nine miles west of Owen Sound, are being rebuilt at a large expenditure, and we expect to have our factory in full operation again about the 1st of November. Some additions are being made to our machinery, and when completed we will be able to turn out even a better grade of cement than in the past, which was always considered equal to any imported cements. By making the above correction, you will much oblige.

Yours truly,

THE OWEN SOUND PORTLAND CEMENT CO.

A SUGGESTION FOR THE O. A. A.

TORONTO, October 6, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Some months ago you mentioned in your paper that the Province of Quebec Association of Architects had opened a reading room and other offices, into which the members could come at any hour of the day or evening, and so on.

Now, what is to hinder the directors of the O. A. A. from doing the same thing. In Montreal the sister association has far more to contend with than we have here. They have not half the number of members, and they have a serious opposition to face which we have not. At our last convention it was considered advisable to do something "to keep ourselves before the public" and show them that we are an association with a definite aim and object, and not to let ourselves be forgotten or overlooked. Now what did we do? We gave a lecture—I will not comment upon it—but we gave a lecture in public, one and only one—and that poorly advertised and worse attended, in a neighborhood not usual for public entertainments. I believe that if we had a fair sized room and had it something like the Montreal arrangement, where we could meet, see each other, discuss common subjects, and have books of reference to study, and so on, and at least a brass plate at the door, the public would know something more about us, and we ourselves could have more interest in our Association. Our management follows a policy of "masterly inactivity." It professes to be doing a great work, but from one year to another, except for a sudden momentary ebullition, I maintain it does little if any good beyond educating—if it does that—the future architect.

Yours truly,

CITY MEMBER.

COMPETITIONS.

The Verein zur Beforderung des Gewerbefleisses, of Berlin, is offering a silver medal and a prize of $750, for the best paper giving a chemical and physical analysis of the iron paints mostly employed. Very little definite information is known regarding the application, duration, effect, etc., of these paints, and the papers above invited should contain (1) a description and classification of the paints mostly used, based on a chemical analysis. (2) A statement of the materials and mixtures which form the most suitable paints for application to all kinds of iron. All papers are to be sent in by the 15th of November next.

According to the permit book in the office of the City Engineer, there have been erected in London, Ont., since the first of the present year, 147 dwellings. Of these 78 are cottages and 39 more pretentious residences. The brick houses erected in the city since New Year's cost upwards of $118,550. In ten instances no figures are given with the permit. The cost of frame houses during the same period was $22,475, with the prices of four not given. Preparations are under way for the erection of a free library building to cost $12,000, while the Y. M. C. A. will erect a $50,000 structure.

THE LONDON, ONT., PUBLIC LIBRARY COMPETITION.

Much dissatisfaction has been caused to the majority of the competitors in the above competition by the action of the Board in awarding first position to a design which in a most essential particular does not comply with the instructions issued to all the competitors. A copy of the specified requirements as forwarded to one of the competitors by the Secretary of the Library Board, is as follows :

[COPY.]

MESSRS. ———— LONDON, June 27th, 1894.
Toronto.

Gentlemen :—In reply to yours of June 26th, would say, Competition is open. We require plan of Basement, showing Lavatory, etc.; plan of Ground Floor ;—plan of First Floor ; Front and Side Elevations.

Size of Building, 50 x 80 feet, of local brick faced with No. 2 pressed bricks.

Basement, size 20 x 50 feet, 8 feet in the clear of St. Mary's or Credit Valley stone, 8 feet to Ground Floor.

Ground Floor to have Librarian's Room, Reading and Ladies' Toilet Room, wood ceiling 14 feet high, pine floor and finished in clear pine.

First Story finished in grey plaster with 14-inch base, no partitions, wall to be at least 7 feet to plate, maple floor.

Roof to be of slate and at least ½ pitch.

Building to be heated with hot air, with gas piping and wiring.

The upper floor to be deafened.

Plan to be drawn to scale of 8 feet to inch.

Elevations to be in black and white.

In case the Building and Heating Apparatus cannot be erected for $12,000 (twelve thousand dollars), the Committee will not pledge themselves to pay any commission.

The successful competitor to receive $600. The man whose plans are accepted to furnish plans, specifications, and superintend the erection of the Building.

Plans to be in by July 3rd.

Yours truly, (Sgd.) C. E. KEENE, Sec.

The CANADIAN ARCHITECT AND BUILDER has also received from a well-known firm of architects the following letter on this subject :

Editor CANADIAN ARCHITECT AND BUILDER.

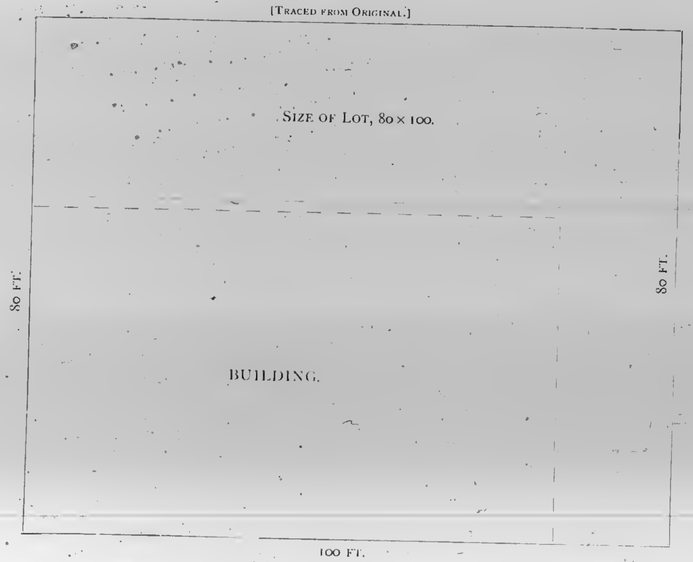
SIR,—The united protest from all the architects who entered the London, Ont., Free Library competition and were so meanly treated by the Library Board, forms but another link in the chain of circumstances adverse to the straightforward practice of the profession of architecture in Canada. It seems inconceivable that a Board occupying such a position of public trust, should have so little respect for justice and fairdealing as to permit the conditions of competition, formulated for the purpose of instructing competitors as to what was required in the proposed building, to be utterly disregarded in one of its most important clauses. Who would dare to assert that it is right to limit all the competitors to a certain clearly defined portion of the lot on which the building is to stand, and at the same time accept the only design which covers nearly the whole of the two sides of the lot—having frontages on each street vastly in excess of the stipulated site? There is something wrong when no steps are taken to rectify such an injustice, although the attention of the Board was at once called to the matter.

The competition was entered upon the district understanding that the design which best met the requirements of a free public library, would be adopted, providing it complied with the proper and reasonable conditions of the Board and of the site. Surely, no sane person would expect reputable architects to devote their time to the elaborate designing of a building, upon the loose understanding that the instructions given did not form part of the competition, or that anything in the way of a library plan would do, if it did not exceed the specified cost, nor, if it did exceed the cost in this case, would it have mattered much? Probably not.

We believe there was an effort made to have the rules of the Ontario Association of Architects, for the deciding of competitions adopted, but without success. The Board did consider the advisability of appointing properly qualified persons to decide as to the best design, but this sensible idea was not adopted. The result is, the adoption of a design which any properly qualified person would have been in duty bound to reject. Probably the small expense of employing competent assistance was the cause of its not being done. It remains to be seen whether they have or have not lost more by the course adopted. The twentieth century is near, and it is high time that qualified architects should demand the discontinuance of this sort of thing. From the personnel of the Board in this case, one would expect considerations of justice to occupy a prominent place. But there has been a wrong done, unwittingly, no doubt, in the first place, but none the less a wrong, and common justice should suggest to them that the least they can do is to try to have it righted.

FAIR PLAY.

[TRACED FROM ORIGINAL.]



Scale of Diagram—20ft. to the inch.

The following protest, in which the fairness of the award is called in question, has been presented to the Library Board :—

To the Chairman and Members of the Free Library Board, London, Ont.

Gentlemen :—We, the undersigned architects, having submitted designs for the proposed Public Free Library, to be erected in London, in accordance with your advertisement of June 1st, 1894, and the conditions furnished by your Board for our guidance in preparing the same, respectfully beg to protest against the acceptance of a design which is not in accordance with those conditions.

We were instructed to make the size of the building 50 feet by 80 feet, and all our designs were made to comply with that reasonable and feasible condition, whereas, the only design which totally ignored that portion of your instructions, has been awarded first place, notwithstanding the fact that it has frontages of one hundred feet by about sixty feet.

We, therefore respectfully beg to submit that we have all been led, by your advertisement, into the expenditure of much time and money, and that in justice to us, you should reconsider your decision, at the earliest possible date, and that the award should be made to the best design conforming to your conditions.

We have the honor to be, Gentlemen,

Respectfully yours,

(Sgd.)	T. A. MOORE.	(Sgd.)	SIDDALL & BAKER.
(Sgd.)	McBRIDE & FARNCOMBE.	(Sgd.)	BEAUMONT JARVIS.
(Sgd.)	M. L. BUFFY.	(Sgd.)	MOORE & HENRY.

(Sgd.) GEORGE R. HARPER, Toronto.

STAINING WOOD.

THIS is a subject few writers in the magazines have touched upon, writes James Marks in Painting and Decorating. It is not so well understood as priming or painting ; it requires a knowledge of wood, its nature and the beauty that a stain is to bring out, or at least not mar or destroy. All woods have a transparent look, or what may be termed reflection ; they change as light strikes them. Look at a varnished door of hard wood in one light, the cross stiles will look darker than the upright stiles. Change your position or change the light, and the reverse will appear. Examine a panel of bird's eye maple, or any curled wood, it will change as the light is reflected on it. This is the beauty of real wood, whether varnished or stained, and is a beauty that no grainer has ever been able to imitate.

To stain wood and keep this reflecting power or change of appearance, is or should be the object. It has been done, it can be done, but it very seldom is done. The conditions are against its being done on the ordinary work that is met with in our every-day experience. The first thing necessary is the wood itself ; it must be clear, and free from sap, soft places and knots. Mill dressed lumber should be finished off with a sharp smoothing plane. No sandpaper should be used on the work ; all ends of mortices should be carefully sized, before staining, so as not to appear dark, by the extra quantity of stain they absorb. No lime or plaster should touch the woodwork, or a dark stain will be the result.

Let us varnish a piece of woodwork of this description, say white pine, with three coats of light hard oil finish, or, better, a good No. 1 coach varnish, and all the beauty of the wood is to be seen. Nothing is marred, nothing hid. Next let us stain and varnish, and the chances are that the fine, satin-like reflection is gone. There is something in the stain that mars the fine transparent reflection which is the beauty of all natural wood finish. The grain may be left, and even be brought out, more prominently by an inferior stain ; but this is not or should not be the object sought for, for if the reflection which changes is destroyed with a filler or a stain, then it should not be used.

The average painter concludes that a coat of thin color that produces the desired tint is a stain, and will, and does, in a number of instances, meet the requirements of a stain best, but this is not a proper stain. No coating of any pigment, no matter how finely prepared, or how applied, in oil or distemper, can be applied to wood as a stain without destroying the real beauty of the wood, the reflection.

It is the natural tendency of all woods to darken under varnish or polish ; how this is cannot be readily accounted for, except it be the action of light on the wood shining through the varnish or polish, either of which excludes air ; but when they darken in this way it is always with a change of color natural to the color of the wood in its native or new state. This can be observed in old oak furniture or mahogany, both of which grow old with a beautiful transparent richness, the color of which should be imitated if possible.

Let me give an illustration : I have a strip of ash or light oak, the grain of which is as near to walnut as possible. This strip is to be stained the color of the walnut, and the reflection is not to be destroyed. The stain that will accomplish this is a proper stain and none other.

Staining has taken the place of graining, and while, on account of cheapness, it may be a substitute, so far as the average job is concerned, that is produced with a coat of stain and filler combined, or color stained, it has neither the beauty nor appearance of an average job of graining, and will not until woodwork is properly prepared and staining is properly done ; then be assured it may compete with graining, but it will certainly cost more money. There must be a new idea formed, and a more correct one, of what is needed, and the makers of stains and fillers must be required to produce a stain that will do the work in a proper manner, under skillful workmen, and not advance claims for their goods that cannot be accomplished.

STUDENTS' DEPARTMENT.

ADVICE TO A YOUNG ARCHITECT.

THE following characteristic letter was prepared by the late Mr. William Burges, at the desire of a young architect, who consulted him about the worthiest course to follow in the study and practice of architecture :—

"My Dear Sir,—I venture to submit the following considerations to your notice :—

"You have passed your apprenticeship, done your Academy, and finished the usual Continental tour, and the question now arises as to what you are going to do ?

"If you follow the usual course, you would take an office, hunt up work, and do the same according to your lights, consoling yourself that many architects would do it much worse.

"Of course, there are various sorts of practice, all of which are open to you, and you might become simply a house doctor, or a warehouse architect, or a light and air man, or an architectural policeman (i.e., district surveyor), or a general partitioner ; and it is quite possible to make money by any of these, the amount depending on the extent of the practice, and that again upon the number of friends, besides the amount of the importunity and imprudence by which work may be solicited.

"But reflect ; are any of these men artists ? It is true that when they die they may have made money, but what else will they leave to the world besides that ? Their names are simply written in water.

"Now, it is quite open to you to take to all or any of these lines of practice, to make money, to bring up a family, to become churchwarden and, above all, to be pronounced 'warm' when you leave this world.

"My object in writing these lines is to suggest to you that there is another course open by which you may perhaps be the means of leaving some beautiful things to posterity, and by which your name may possibly survive after you have quitted this life.

"The question arises, 'Why not try to be an artist, an accomplished man, a creator of works of art, and an ornament to your profession ?'

"You have not the excuse that many have for not making the attempt, as I understand you are in a great measure independent of your profession.

"Why not use that advantage to be something more than an idler on the one hand or a money grubber on the other ?

"Try at least for a couple of years. They will not be lost years, even should you eventually not take up the artistic branch of your profession ; for you will to a certain degree have educated yourself in the attempt, and you will be so much the better.

"Supposing you decide to try, let us see where you are. You know something of modern construction, enough to enable you to practice without letting your buildings fall. You can draw well, and in an architectural and geometrical manner ; but I know nothing of your perspectives, and your freehand drawing is woolly, and wants precision. Above all, you are very defective in the human figure. (You have, I presume, a fair knowledge of the history of architecture.)

"Now, I should recommend you to employ your next two years in three principal things :—

"1. The drawing of the human figure. This is easily the foundation of all good taste. I don't mean that you should spend weeks in frizzling up a figure in chalk, for you are not going to be a painter, but that you should learn to draw correctly and know the bones and muscles which go to make up the outline, and, in fact, to be able to account for everything you see.

"2. A serious course of reading of the best and well-known authors. This also will conduce to form your taste. Philosophy and science will not help you so much as works of the imagination. Bohn's Library furnishes fair translations of the best authors at 5s. per volume ; but if the work is a translation, it is desirable to get two or more versions and to compare them together. In the Classics, I should recommend Homer, Aristophanes, Æschylus, Herodotus, Xenephon, Virgil, Horace, Apuleius. Of the moderns, Dante, Chaucer, Shakespere, 'Faust,' 'Robinson Crusoe,' 'Undine,' and Lane's translation of the 'Arabian Nights.' Of course I could mention many more, but these are sufficient for the present.

"3. To carefully study and draw various beautiful things ; and whether the said thing be a piece of jewellery or a piece of iron work or a building or portion of a building—to do it thoroughly, to find its construction, and why this and that is done, the basis of the ornamentation, the particular form of the curves, and never to leave it until you know all about it. The result will be that the next time you see a similar thing you will know all about it, and won't want to study it again. Do everything by common sense ; don't make a drawing when you can make a rubbing, and regard all your drawing in the light of evidence which is worth next to nothing if it is not authentic.

"I consider you very lucky that you have such an opportunity of having your 'learning time' over again, and I am quite sure that if you make up your mind to be industrious, your two years spent in the way I have ventured to suggest will be very happy as well as very useful ones.

"Hoping you are not bored by the above.

I remain, yours truly, "W. BURGES."

ANNUAL MEETING OF THE PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE Province of Quebec Association of Architects met in annual session on Thursday, October the 4th, at 10.30 a.m., in their rooms in the New York Life Building, Montreal, the President, Mr. J. Nelson, in the chair. Among those present were: Messrs. J. Nelson, President; C. Baillairgé, Vice-President; A. C. Hutchison, 2nd Vice-President and Acting Secretary; J. Z. Resther, Treasurer; A. T. Taylor, E. Mann and J. Venne, Councillors; S. Lesage, A. F. Dunlop, Jos. Perrault, L. Z. Gauthier, H. C. Nelson, V. Roy, J. Z. Resther, F. X. Berlinguet, G. A. Monette, T. Daoust, M. Perrault, W. E. Doran, W. McLea Walbank, G. W. Wood, A. H. Lapierre, J. R. Gardiner, A. Boileau, etc.

The annual report of the Council, read by the Acting Secretary, stated that at the semi-annual examination in January four candidates presented themselves for admission to the study of architecture. Of these three passed. During last winter arrangements were made for the members of the Association resident in Montreal to meet once a month at dinner and subsequently to listen to papers and lectures. The Council regretted that these opportunities for social intercourse and instruction were not taken advantage of in the manner it was thought they would have been. Early last fall the Council endeavored to form classes for students engaged in architects' offices, in order to afford instruction in branches of study not usually obtained in an office, and so prepare them for passing their examinations. It was regretted that owing to the difficulty in obtaining teachers and to the lack of interest in the matter by members and students, these classes had to be abandoned. The Council strongly urged upon the Association the necessity of establishing classes for the systematic study of the several branches of architecture, either in direct connection with the Association or in connection with an university. During the year the number of books in the library has been slightly increased by purchase and donation.

The report submitted by the Treasurer, Mr. L. Z. Resther, was of a very satisfactory character.

The reports of the Council and the Treasurer having been adopted, the election of officers was proceeded with, and resulted as follows, the scrutineers being Messrs. E. Mann and A. H. Lapierre:—

President—Mr. Charles Baillairgé, Quebec.
1st Vice-President—Mr. A. C. Hutchison, Montreal.
2nd Vice-President—Mr. A. T. Taylor, Montreal.
Secretary—Mr. J. Venne, Montreal.
Treasurer—Mr. Joseph Perrault, Montreal.
Council—Messrs. A. F. Dunlop, J. Nelson, A. Raza, L. Z. Gauthier, Montreal; F. X. Berlinguet and J. B. Bertrand, Quebec.
Auditors—Messrs. L. Z. Resther and W. McLea Walbank, Montreal.

The most pleasing part of the morning session then took place. It was the presentation of a large photographic group of the Montreal members of the Association to their confreres in Quebec. The photograph, which is placed in an antique frame, is a really fine specimen of the photographer's art. Mr. Jas. Nelson having explained that he and Mr. Taylor had been charged by the Montreal members with the arrangements for the picture, called upon Mr. Taylor to make the presentation. That gentleman alluded to the fact that the Montreal members had already received a photograph group of their Quebec confreres, and the former felt that the least they could do was to reciprocate as soon as possible. It was hoped that the photograph would be received and kept by the brethren in Quebec as a pleasant memento, and that for many years to come their successors might look at it and see the gentlemen who started the Association and carried on the work for so long.

The newly-elected President returned thanks on behalf of the Quebec members, and spoke of the artistic merit of the picture, saying that although the idea of the Quebec and Montreal sections of the Association presenting photographic groups to each other had perhaps originated with the former, the latter had improved upon it in many ways. The photograph represents forty-three Montreal members of the Association assembled in a handsome room, the background being a reproduction of a view of the Senate Chamber in the Palace of the Doges in Venice.

Mr. F. X. Berlinguet also briefly returned thanks, after which the gathering adjourned for luncheon.

AFTERNOON SESSION.

The newly-elected President occupied the chair at the afternoon session, which opened at 2:30, and contributed the following paper:

FOUNDATIONS IN DEEP AND UNRELIABLE SOILS.

An article in the Engineering Record of New York, on "Foundations of High Buildings" by W. R. Hutton, M. Am. Soc. C. E., etc., has reminded me that in the Province of Quebec we have had several failures of an expensive nature to make good, due to faulty foundations as at Joliette, St. Bazile, St. Casimir, Nicolet, etc., and in Upper Canada at Cornwall and elsewhere.

As it is more satisfactory to know exactly how the foundations of certain tall and heavy structures have been built, than to learn from any treatise on the subject how they should be laid down, I shall first summarize Mr. Hutton's article as extremely interesting and instructive to the profession, and then allude to the Canadian cases mentioned. In New York the rock is at from 15 to 50 and 70 feet below the surface, and overlaid by yellow sand mixed with clay and containing pockets or beds of quicksand. Many buildings rest on piles driven to refusal, though not necessarily to, nor always to, the rock. Under the city building law, each pile may be loaded with 20 tons. The permanent wet level is about that of high tide in the harbor and piles, not to decay, should be cut off at or about this level—dry seasons and deep drains, which may lower it being taken into consideration. When a gap occurs in the rock and bottom can not be reached, an arch is thrown over to carry the walls above it, as was done in the case of the Washington (Field) Building on Battery Place.

The method of founding directly on the sand is gaining favor. The "Equitable Building" and the "Union Trust" are so built with wide footings loading the soil to 2 and 2½ tons to the square foot. The "World" and "Times" buildings have similar foundations. Older buildings at only a few feet below the surface have suffered, probably from the lateral flow of quick-sand into deeper neighbouring excavations. The newer buildings are at too great a depth to render such a result at all probable. When test pits are sunk and quick-sand makes its appearance, endangering adjoining structures, concrete should be at hand to promptly fill the pit and prevent the danger.

To save the cost of 15 to 20 feet of underpinning to the old walls of contiguous buildings, the foundations of the "Methodist Book Concern" were built in alternate piers surrounded with sheet piling; the intermediate piers then put in; the whole arched over and the walls raised upon them. In the case of the "Manhattan Life Insurance Building" 353 feet high above street level, with foundations 55 feet deep to rock—a total of 408 feet—piles enough could not be driven to bear the great weight. The system adopted was that of pneumatic caissons. Fifteen of them, of which eleven are square, varying from 13×13 feet, to 21×26 feet, and four circular ones from 9 to 15 feet, in diameter, cover some 4,000 square feet, or about half the area of the site. The coll-ective area of the caisson is proportioned to the maximum pressure allowed by city regulations, namely, from 150 lbs. to the square inch (say eleven tons to the foot), the brick piers being somewhat smaller as they may be loaded to 200 lbs. to the inch, 14½ tons to the foot. The caisson roof is strengthened with I beams. The whole area is excavated to 20 feet in depth below the Broadway level, and the caissons are sunk by means of compressed air 35 feet further to the rock. They pass through 12 feet of fine micaceous sand, layers of mud with sand, of silt, of clay mixed with sand, and a very hard conglomerate over the usual gneiss rock. The caissons were sunk by excavating the soil beneath them from the inside, and by the weight of the brick piers simultaneously built upon them, and to avoid an inflow of quicksand which might occur when the air pressure was reduced by blowing out the semi-fluid material through pipes, it was decided in the beginning to remove all material in buckets through the air locks, but upon trial it was ascertained that the pressure could be maintained while blowing out by running the compression faster, and the soft earth was thus removed. It is to be noted that any flow of quicksand from outside the lines of the caisson might have caused settlements of the neighboring buildings. When the caissons reached the rock they were filled solidly with concrete. "At the date of writing," says Hutton (September, 1893), "nearly all the caissons had been sunk to place and no appreciable cracks had occurred in adjacent buildings, one of which rests on piles at the level of the general excavations (20 feet below street level as already stated), the other on the natural soil several feet above." The cost of these 55 feet foundations is said to have been ten per cent. of the entire cost of the building. A commendable feature in the "Manhattan Life Building" is the symmetrical distribution of the load upon each pier. Commonly foundation walls are built upon the outside edge of the property, with the footings almost entirely inside the thickness of the wall, concentrating upon the outer edge of the foundation pressures much above the average. In the "Manhattan Life," the supports are centrally or symmetrically placed upon the caissons, and strong steel girders extending from side to side of the building sustain the side walls in "Cantilever," to borrow a form of expression from the French. The engineer-contractors of the building, Messrs. Snoozsmith & Co., made an interesting application of the same method in founding the draw pier of the Seventh Avenue bridge, New York. This is a circular pier 59 feet in diameter. Their experience having convinced them that there was great risk of cracks in the masonry from irregular movements of a very large caisson, this one was made annular in plan, 59 feet in outside diameter and 10 feet wide. When sunk upon the site, cemented to the rock and filled with concrete, it formed a "cofferdam within" which it was expected to build the masonry "in the dry" after the water was pumped out, but seams in the rock bottom of the central space admitted water faster than it could be removed by pumps, and it became necessary to cover the bottom with a layer of concrete put in place under water to close the seams and permit the completion of the pier.

In Chicago, foundations are more difficult and costly, due to the fact that instead of only 30 feet to 50 feet, as in New York, there is from 60 to 100 feet of blue drift clay overlying the rock, a material having a greater avidity for water and containing beds of quick-sand, and yet upon this soil Chicago boasts some of the highest buildings yet erected. Formerly platforms of timber were imbedded in the clay, and piles rarely driven to the rock, but the great weight of recent structures requires that piles be driven to the rock, and the tops cut off below all future drainage, that they may be always "in the wet", or detached foundations under each wall and pier, with footings carefully proportioned in area to the weight to come upon them and to the resistance of the soil. The best practice limits the weight to 3,000 lbs. per square foot, or say 1½ tons, but this is frequently exceeded. Some settlement is expected, and it is sought, by proportioning surfaces to weights as far as possible, to render the settling uniform.

As the wide footings when of masonry must be built in high and narrow offsets, forming a truncated pyramid under each pier or wall, thus robbing basement floors of much of their height, the practice in Chicago and elsewhere, due to the comparative cheapness of iron or steel bars and beams, is to form the footings of tiers of these bars laid on a concrete foundation, each successive tier laying across or at right angles to the one below, or along and across the wall alternately, and as their greater transverse strength allows of a greater breadth of offset, the reduced thickness of the walls is reached more rapidly or in a lesser height, not exceeding from 18 to 30 inches instead of from 7 to 8 feet in some cases where of masonry. The weight is said to be also thus reduced by about 4 per cent. of the load upon the pier. The bars or beams sometimes of second hand railroad iron, are first dipped in hot asphalt or tar, carefully bedded on and filled in, and covered with concrete to protect the metal from rust. Such a foundation is of course, dependent on being at such a depth that the adjoining soil be undisturbed. As on account of the soft nature of the clay, as glaziers' putty, it must flow laterally if not prevented from doing so, just as water supporting a vessel in a lock would do, or dry sand, any structure, if not laterally retained by some solid surrounding. Some large buildings in Chicago have been erected upon a continuous platform of concrete, covering the whole area of the structure. The serious, irregular settlement of a prominent public building constructed in this way, accompanied by cracks in the walls and in the concrete platform, has brought the method into disfavor. It has been applied with better results when the platform has been made with iron beams covered and protected with concrete.

It has been observed in Venice, a city founded on the marshy bottom of a lagoon, that many large buildings constructed in the 14th century and before, rest upon a platform of masonry broader than the building it supports. The masonry itself rests upon a bed of puddled clay which shows signs of a powerful artificial compression. These structures show no notable change, while many others of later date, built upon piles, show by numerous cracks the irregular settlements they have incurred. It is said that the tower of St. Mark's does not rest on piles.

A different method has been adopted for a part of the foundations of the new "Stock Exchange" in Chicago. The foundation is generally upon piles about 50 feet long driven into the hard clay which overlies the rock; next to the "Herald Building," however, which adjoins it, wells were substituted, lest the shock of the pile driven close to its walls should cause settlement and cracks. A short cylinder 5 feet in diameter, made of steel plates, was first sunk by hand, reaching below the footings of the Herald building. Then around and inside the base of the cylinder, sheet piles about 35 feet long were driven, and held in place by a ring of steel inside their upper ends. The material inside the sheeting was excavated, and a similar steel ring was placed inside their lower ends; by means of wedges the lower ends of the sheeting were forced back into the soft clay, until another course could be driven outside the lower ring. This operation was repeated until the excavation had reached the hard clay about 40 feet below the cellar. In this material the excavation was continued without sheeting, in the form of a hollow truncated cone to a diameter of 7½ feet, and the entire excavation was filled with concrete. The wells are spaced about 12 feet, the loads upon them vary; some of them will carry about 200 tons—something less than 4 tons to the square foot. The material excavated was a soft putty-like clay to a depth of 40 feet, where a firm clay was reached, deemed capable of carrying the weight proposed. The rest of the foundation is upon piles spaced 3 feet between centres, to be loaded with about 30 tons per pile, similar piles having been tested to 50 tons at the Chicago Library foundation. They are driven with a Vasmyth steam hammer without brooming, are cut off below lake surface, capped and filled in with concrete. A series of short transverse I beams distribute the load transversely, and longitudinal beams prevent local settlements.

The foundations of the Washington monument at Washington have heretofore been well described, but having been commenced in 1848, now some 45 years ago, a description of the method employed may not be uninteresting or uninstructive to the younger members of the profession. This structure, when I visited Washington in 1856, had obtained a height of 156 feet. The monument was commenced on a national subscription then limited to $1.00 per head, to afford every citizen the advantage of contributing his mite towards honoring the memory of the great man whose name it bore, and I myself have the honor of being one of the original subscribers, the receipt for which, of the size of an ordinary bank note, engraved on white paper of the consistency of a bank of England note, with a cut of the finished monument at one end of it, I probably still have in one of my souvenir albums. Almost every nation of the earth had contributed a souvenir in the shape of a block of its most precious stone or marble, bearing a fitting inscription, and which were so placed as to be seen and felt and read step by every one ascending the inner stairway, reaching, at the time of my visit, to the then top of the structure, and intended to be continued upwards to the full height of 600 feet then proposed; while hundreds of similar blocks from all the crowned heads of Europe, not excepting His Holiness the Pope—blocks of solid copper and nearly solid gold and silver and the like, were either incased in the monument or lay strewn about the ground awaiting each its turn to do honor to the "Father of his Country," the hero of liberty and independence.

At the date of my visit the works had been for some time interrupted, owing to unequal settlement of the foundation. In 1878, says Hutton, the work which had been in the hands of the Washington Monument Association was turned over to the general Government and completed with money appropriated by Congress. The work as finally constructed is a plain shaft 500 feet high with a pyramidion on top of it 55 feet in height. The shaft is 55 feet square at the base, 30 feet at top, the interior being say 20 feet in diameter, and weight over 90,000 tons. The original foundation was of rubble masonry in lime mortar, 23½ feet thick and 80 feet square at the base, the footings thus projecting 12½ feet all around beyond the outer lines of shaft. The soil upon which it rested was a sandy clay; 13 feet below this was a bed of gravel. The area of the base was too small, and the soil under it not sufficiently resisting to carry the final weight. A mass of concrete 13½ feet thick, extending 23 feet 6 inches outside of the old base, and 18 feet under it, increased the bearing surface and carried it down to the gravel. The concrete extended 5 feet under the walls of the shaft itself. The construction of this block of concrete under a shaft 156 feet high and weighing 36,000 tons, was a delicate operation, accomplished in this way:—On the east and west sides, near corners diagonally opposite, cuts or trenches 4 feet wide and 13½ feet deep were made from the outer lines of the foundation, and extended by tunnelling 18 feet under the base of the old foundation. When completed they were filled with concrete, and other cuts opposite to them were made in like manner, carried under the old base and filled with concrete. The removal of so much bearing surface in these two tunnels under the old foundation was sufficient to cause motion in the structure, and after this but one cut was made at one time. The work was continued and completed by this system of narrow cuts, which were filled with concrete until the entire sub-base was finished. After this, 10 feet in thickness of the outer part of the old foundation was removed in sections 10 feet wide and replaced with concrete extending 10 feet out on the new base.

Being under the impression that when I saw the monument, at that time 156 feet high as stated, it inclined somewhat out of the perpendicular, and as Mr. Hutton in describing the underpinning and strengthening of the foundation did not allude to the fact, I wrote him through the Engineering Record and my letter and his answer appeared in a recent issue of the journal, to the effect that it did incline slightly, but that its rectification was effected through the process of underpinning, though he does not say precisely how. I remember, however, that previously to strengthening the foundations in the manner described, it had been proposed to excavate beneath the monument, introduce a series of upper and under sills of heavy timber with uprights or posts between them, introducing some hundreds of jack-screws and letting down the monument gradually on one side to the level of the other. This process I applied myself in a modified form and on a smaller scale in bringing back to verticality a factory chimney some 80 feet in height at Hook's mills, in Grant street, Quebec. After cutting away a wedge shaped slice of the brick work from beneath the shaft, or between it and its foundation, by means of jack-screws it was let down by so much, the thickness of the wedge sawed out bearing the same proportion to the breadth of base as did the inclination over to the height of shaft, which inclined some two feet from the perpendicular.

Gravel and sand are counted among the incompressible materials for foundations, when prevented from spreading sidewise. The resistance to lateral spreading is usually furnished by the adjacent sand, and when this is insufficient the surface rises as the building sinks, precisely as water does around a vessel in a lock, with the additional weight of an in-going cargo.

I have said that from faulty foundations several Canadian structures have been wrecked to a considerable extent, but I shall only here allude to the new Joliette church, from having myself seen it now two years ago, and the blame ought to be fixed somewhere for a fault which it will probably cost all of $10,000 to make good. The tower of this fine edifice, when I saw it, had actually sunk not less than eleven inches below the adjoining masonry of the sides, tearing itself away completely from the adjoining walls or remainder of the facade; and as lateral portions of the facade had also sunk, though to a less extent, and were bringing down the side or aisle walls of the edifice, the church wardens had the whole front of the facade cut away from the sides to allow of any future sinking of the tower without dragging the sides with it to destruction. The other churches I have mentioned as at Nicolet, St. Casimir and St. Bazile, have been affected I am told, exactly in the same manner, and due to a similar cause, to wit, the omission on the architect's or contractor's part to so proportion the breadth of footings as to cause every square foot thereof to bear an absolutely equal load on such a soil as at Joliette, where there are some eight feet thick of sandy clay overlying some 20 to 30 feet of mud or of clay of such a soft and semi-liquid nature that anyone can drive an iron rod into it to a depth of 20 feet or more. And this proportioning of the area of footings is such a simple thing to calculate that it is criminal to say the least, to neglect doing it. Again, in this case of the Joliette structure, the foundation I am told of the tower and remainder of the front elevation were sunk to a greater depth than those of the aisle walls, a very foolish thing to have done, as it left less of the comparatively solid upper stratum of sand between the wooden platform under the walls and the soft clay below, thus increasing the tendency of the heavier walls to penetrate into the soft substratum. Now the architect who planned the structure, it is said, disclaims all responsibility in the premises, as not having been employed to superintend the construction of the building; and the contractor says that neither is he responsible as he executed the plans as prepared by the architect, and so between them both it appears that the parish will have to foot the bill of reconstructing the whole facade and tower at the parishioners' expense.

I had the honor at our last meeting in Quebec of reading you a paper on the "Necessity of a School of Architecture for the Province of Quebec," or I should more aptly have said, "for Canada as a whole," since similar failures have occurred in Ontario; and now I presume it will not be denied that such a school is of paramount necessity, where an aspiring architect may be taught the importance of sounding and boring the soil he plans to build on, and in any case where not on solid rock or an unyielding base, not fail to spread his footings in a way to make them truly proportional to the respective weights they will have to bear.

Errors so expensive to make good should not occur again as at St. Bazile, where the walls sank some two feet, and the masonry had to be almost entirely rebuilt at a cost of some $12,000. At Cornwall, the settlement was not less than two feet ten inches, and occurred all at once, I am told, on or during a single night—the front wall tearing itself away from the remainder of the church and sinking bodily and equally, though, or in a way to allow of making good the levels of the door-ways without the necessity of demolishing and rebuilding the front and tower.

Foundations may be considered the engineering part of architecture, and it is strange and hard to see how, while an engineer will never attempt to drive a pile or sink a caisson or start the foundations of any structure without sounding the soil he has to build on, an architect can consider himself less liable to the danger of unequal settlement. The CANADIAN ARCHITECT AND BUILDER, in an article in its November issue of last year, insists on this engineering knowledge on the part of architects, and it is to be hoped, that the absolute necessity of the thing will now be seen and not forgotten in the future.

Not settlement is to be guarded against, but solely inequality of settlement in the different portions of a foundation. It is just as easy to erect a heavy structure on a mud foundation and insure its permanent verticality, as to cause a heavy iron-clad to ride at ease and upright on its bed of water. This can be done, as said, by thoroughly proportioning the area of base of each portion of the structure to the weight it has to bear, which will insure absolute equality of settlement in any homogeneous soil; but if one or two corners of a structure be on rock or any such unyielding foundation, then becomes it peremptory in the other portions to reach the rock or rest on it by the proxy of piles or pillars driven down to an equally unyielding bottom; or if not, to see by trial how much the soil can bear without sensible compression, and divide the weight, or spread it out over such a number of feet as will meet the requirements of the case. If a reliable bottom is to be reached by piling through a bed of stiff or compact and so to say incompressible sand, it must not be forgotten that material aid can be had by applying the loosening, disintegrating power of water. I had to do this myself when boring in 1876 for the tests as to the nature and impermeability of the soil or river bed to be built on. The sand was so compact that a two or three inch tube could not be driven into it to more than a few feet without the aid of a jet of water forced down through an inner and smaller pipe, and which loosened and disintegrated the sand beneath the outer pipe in a way to cause it to sink to a depth of 70 feet to rock bottom, while room was made for the advancing pipe or pile or borer by the water forced down, as said, through the inner tube, coming up or returning through the space between the tubes and bringing up the loosened sand with it. Ordinary wooden piles may be driven in the same way through stiff and otherwise unyielding soil, by the use of water under pressure forced down through a pipe or hose attached to the side of the pile and reaching to its shoe or point, and easily removable, and to be used again on each succeeding pile. This most effective mode of loosening the soil is much used and has been for some years past, in pursuing excavations under water, and in fact, in all possible situations, and the material removed, it must be remembered, can now, instead of having to be so removed by cartage, be blown away to any distance by forcing it through pipes of adequate size or even rubber or canvas conduits under air pressure, or which is the same thing, by pumping out the air in front or ahead of the material to be discharged or removed, when the mere atmospheric pressure of over 2,000 pounds to the square foot blows the stuff along to destination.

The most advanced practice in caisson foundation building, is perhaps that now being pursued in putting in the piers for the American Surety Company's building in course of erection opposite Trinity church, corner of Broadway and Pine street, New York, by Bruce Price, architect of the new Frontenac Hotel, Quebec. These foundations are 70 feet deep to bed rock, while the building of 22 stories, or 360 feet in height above road level, and therefore higher than Trinity church itself, will have a total height of not less than 430 feet, its cost being put down at some $2,000,000. Messrs. Snoozsmith & Co. are the engineering firm of contractors. I say "engineering," because now-a-days, the responsibility for solidity and permanency of construction, devolves on the contractors equally with the designing architect. These firms of builders employ the highest engineering talent, for it must not be believed, as popularly thought, that all the engineering difficulties are in advance wrought out and solved by the designers, on the contrary, Sir Benjamin Baker, in the construction of the Forth bridge, where the twin

spans are each some 1,700 feet from pier to pier, gives the greatest credit to the contractor's engineers for their many ingenious devices in carrying out the work. In the case under consideration—the American Surety Company's building,—there are (13) thirteen brick piers on as many rectangular steel built caissons of ½" stuff, braced on the inside. The caisson is 7 feet high beneath the roof of heavy I beams, its sides carried up two feet all around above the roof, with a two feet filling of concrete on which the brick piers rest. The whole foundation was excavated bodily, and taken out down to 20 feet beneath the roadway, at which depth water was reached. The caissons were then put in place—not all of them together, but in alternate series, so as not to risk deranging the foundations of adjoining structures, sunk to a lesser depth than that to be arrived at. To each caisson is applied a tube of oval horizontal section, and of such size, some 3 x 5 feet inside drain, in the clear of jointing flanges, as to allow of the men passing up and down, to and from their work, and to give passage to the buckets, go and come, by which the excavated material is raised from within the caisson to the surface. The brickwork upon the caisson progresses as the caisson sinks gradually to destination with its increasing burden of advancing masonry. As the pier advances or is added to in weight, additional lengths of iron shaft, or well, or vertical tunnel-way, are added and bolted on, air-tight of course; and as the shaft gains height, the air lock rises with it. The construction and use of the air lock, though presumably well known to all, from having now so often and for so many years been used, as in the construction of piers of the Brooklyn Bridge and elsewhere, is a mere cylinder, a component portion of the shaft, high enough and of sufficient size for several men to stand in at a time. It has an under and an upper door or hatchway, through which the workers in the caisson pass up and down or to and from their work. If there were no water to contend with, the simple shaft way through the pier would be sufficient, the men working under ordinary atmospheric pressure, but the water has to be kept out to allow of excavating to the required depth to reach the rock. The pressure of the incoming water is counteracted, resisted by the pressure of the air from within the caisson outward. This pressure increases with the depth, and hence the necessity of the air back, wherein, while the ingoing and outgoing gang or band are in it, the pressure of the air, by opening a cock in the floor for the ingoers, one in the roof for the outgoers, is gradually increased or diminished in a way to accommodate the lungs and give no trouble to the individual —cause him no discomfort. This would seem to be slow work, but on the contrary, it is, under the trying and difficult circumstances, very rapid, when we consider that as much as 52 feet has thus been sunk in a single week, or nearly nine feet per diem, which would entail a delay of only 13 weeks or a little over three months if each pier had to be sunk separately to destination, whereas three to four of the piers can proceed stimultaneously, and the work be done in a month or a little more.

In the manipulation of the caissons, great ingenuity is shown, to remove no more earth than that which is vertically under the caisson, to avoid disturbing adjacent buildings. In sinking caissons in river beds, no such precautions have to be observed, and the material excavated in semi-fluid state can be blown out instead of bucketed out, as was done in the case of the Brooklyn bridge foundations, where on one side of the river, after the caisson reaching bottom at 40 feet depth of water, there remained 40 feet of sand still to be removed to reach the rock foundation, and this immense mass of some 70 × 100 × 40 feet, say 10,000 cubic yards, was actually blown out by air pressure through the twelve four inch pipes provided for the purpose,—two to each of the six compartments into which each caisson was divided—the pipes running from the floor level of the caisson, through the roof thereof, and up through the masonry as it progressed, with an elbow at the top of each, throwing the stuff out into the river. A caisson for the foundations of a building has also sometimes to be moved laterally, and this is done and has been done effectively, with its load of brickwork on it, by thrusting it forward by struts and jack-screws from the off-side, while the on-side, or that to which the pier is to be moved, is caused to be gradually worn away by the disintegrating action of water already alluded to, the operation being performed by jets of water under pressure, some of them from above downward, while others as effectively do their work from beneath the lower edge of the caisson upward.

Mr. A. T. Taylor also contributed the following paper:

NOTES ON SOME ASPECTS OF THE CITY OF THE FUTURE.

MANY fanciful pictures have been drawn in literature of the condition of man in the future on this earth, most of them with more than a strong tinge of romance. There seems no doubt that in the near future the hygienic conditions of life will be greatly improved, and that the physical surroundings will more and more be laid under tribute to minister to the well-being, comfort and pleasure of mankind. It behooves our profession to be in the forefront of all such movements.

As a population aggregates at particular centres, and crowds together to make up our large towns and cities, problems of how best to house and minister to its physical, mental and higher nature, present themselves for solution to all earnest-minded men. The wise solution of such is not optional, for if neglected or ignored they bring their own Nemesis in misery, disease and death.

In a city's growth there are two elements which go to make the ideal in what we may call its externals, viz.: 1st, wise and comprehensive building by-laws; 2nd, wise and artistic guidance in the laying out and beautifying of its conformation, its buildings and their surroundings, and general embellishments. These two aspects concern us very closely as architects, and I think need no apology for being brought before you to-day.

The necessity for the first of these has been more recognized than the second. Most towns of any importance have formulated some kind of building system to govern the erection of buildings, their general strength and healthiness.

In the case of our own city, the present by-laws have been amended from time to time, and are still somewhat inadequate, so that it is felt by many that the time has come when an entirely new building by-law should be prepared; and as you have heard from the Secretary's Report to-day, a Committee of our Association is working upon this at the present time. It is no easy work—nay, it is impossible, to frame such laws as to please everybody, or to cover every possible contingency; but it shou'd be the desire of such a committee to frame them so that good building—both as regards materials and workmanship, may be the result, and bad building discouraged. It is unrally, of course, follows that such laws require to be enforced, and they will need firm and judicious enforcement.

Many new materials are employed and many new modes of building adopted, so that building laws of to-day require to be more extensive and all-embracing than of old. It is proverbial that a skilful, and if there is such a thing, an unscrupulous lawyer, can drive a coach-and-six through any Act of Parliament, and it is difficult to make by-laws that unscrupulous jerry builders and dishonest contractors may not evade, or that ignorant and stupid men—architects in nothing but the name—may not stumble and blunder over. It is in checkmating the one and helping the other that these laws will be most useful, and with the plumbing by-laws recently enacted, incorporated, the result should be a reduction in the death rate, fewer fires, healthier homes, and greater peace and contentment. Only in a very general way can such by-laws take cognizance of the design and appearance of the buildings. Were it possible to get a proper authority, thoroughly competent, to criticise and pass judgment upon all designs of buildings to be erected, it would no doubt be an advantage to the appearance of our streets, and such abortions and hideous eccentricities as we are all, unfortunately, too familiar with, would never see the light. But this authority would have to give the widest latitude in choice of style, and any special predilection on the part of such authority in favor of any particular style would have to be controlled. The tendency of all such tribunals is to stereotyped forms, which would have to be avoided, but the careful selection by such a tribunal of men of undoubted ability, but with opposite predilections as to styles, &c., would effectually check this. Personally I am in favor of such a tribunal, but such must be selected, not for political service or as nominees of any party, but for their recognized artistic knowledge and abil ty.

In Europe certain restrictions as to the he ght of buildings have long been in vogue:—Thus, in Paris, no front wall on any street can be higher than 65 ft.; in Vienna the limit is about 77 ft., and in London, in new streets less than 50 ft. wide, the height of a building must not exceed its distance from the opposite side of the street. The wisdom of such rules is now being recognized by our neighbors across the border, where "sky scrapers" have so flourished as to utterly destroy the unity and symmetry of the streets; and enactments are being passed in some cities limiting the heights of buildings. It may be that in the near future some such enactment will be necessary in our own city.

In France, I understand, they go further than this, and the municipal authorities of the cities have supreme control over the treatment of the exterior of buildings—the style of architecture adopted, etc.

I referred to the danger of stereotyped forms in designs controlled by a tribunal of fixed predilections, and I would take the opportunity of referring in this connection to a similar and more imminent and grievous danger in connection with the designs of all government buildings emanating from a department of the government. A well-timed letter from one of our profession in Ottawa appeared in the last number of the CANADIAN ARCHITECT AND BUILDER, which all would do well to read. The system has been felt to be unsupportable in the States, and, as you all know, a bill has recently been passed to throw open the designing of public buildings to the profession at large. Without disparaging in any way either our Dominion or Provincial government architects, I think I will have the unanimous support of all, when I say that, in the nature of the case, better results would follow if wise selections of architects were made from the profession at large for such buildings.

We pass on to the second aspect, viz: Wise and artistic guidance in the laying out, beautifying and embellishment of the streets, parks, buildings and surroundings of a city. This has been grievously neglected. Cities have been allowed to grow either at haphazard, like our own city, and then millions of dollars expended on widening the streets and cutting new ones through dense population; or have been laid out in simple grid-iron plan, as prosaic and inartistic as it is possible to imagine. The relation of a building to its site and the relation of the site to the building, has been too often ignored by authorities and by architects. As an example of the first, I may cite the new Boston Public Library, which is, to my view, very unsatisfactory in relation to its environments; and as examples of the second, I may refer to nearly all of our public buildings, which are planted down without any regard to vistas, or of being made central features in our streets. Paris is a notable exception to this, and in the laying out of her squares, gardens and streets, and in the arrangement of her public buildings and monuments, she is an example to the world.

On this continent, Washington is perhaps the best laid out city for such effects as I have named. All cities of the future, which are not simply the development of the cowpath of the country and the lane of the village, will be laid out with some regard to numerous open spaces, radiating boulevards and noble buildings, placed in such positions as to afford beautiful vistas. There will be more gardens and parks, because men will have learnt that these are greater moral factors in the well-being of mankind, than crowded tenements and low saloons.

Charming effects in cities are often obtained by curved streets of large radii. Who has not delighted in the windings of the Strand and Fleet Street in London, or endorsed Wordsworth's encomium on the beautiful High Street, of Oxford, when he describes it as "The stream-like windings of that glorious street?"

I have touched on the designing of public and government buildings. I would like to venture a word or two on the selection of our monuments, statues, and the embellishment generally of our streets, public squares, etc.

Is it not the truth, that very few of these are satisfactory to a cultured taste? In nearly all large cities and towns, monuments, statues, &c., are often so inartistic, so unworthy of their position, that we are led to wonder what dreadful crime the unfortunate man committed that he should thus be held up to the ridicule and pity of future generations. We are not wholly innocent of examples of these ourselves—nay, in many respects we are very guilty. Under existing arrangements, is it surprising that this should be? It would be surprising if it were otherwise. The selection and arrangements for these memorials and adornments are generally in the hands of men—very worthy, no doubt, but not educated in art, and therefore not capable of deciding such matters. It is extraordinary how intelligent men will wisely consult lawyers on all legal questions, doctors on matters of health, engineers on matters of drainage, hydraulics and machinery, but on matters of art and taste, think they are quite capable of judging for themselves.

I have long cherished the dream, that in the city of the future, all such questions will be relegated to a special artistic authority or tribunal, who will decide such matters. Is it too much to hope that this may be realized in the near future in our own city? This is by no means a Utopian idea, for such a scheme has already been put into operation in Boston, where they have succeeded in getting an Art Committee appointed to supervise all such matters as I have spoken of. There the Committee is composed of five members, who serve without any remuneration and consist of the following: The Mayor of the city, the Chairman of the Trustees of the Public Library, the President of the Institute of Technology, the President of the Art Museum and the President of the Society of Architects. Would it be possible to have such a Committee appointed here? It seems to me that some of our worthy aldermen must be exceedingly perplexed, when they try honestly and conscientiously to decide matters of taste and art, and that they would gladly hail the assistance of such an Art Committee, who could give an "ipse dixit" on these things.

We have made marvellous progress in art matters in the last few years, but there is much still to be accomplished if we won'd not be outstripped by other cities.

The art attainment of a people is a measure of their civilization. I think it is quite within our province as an association of architects to take the first step in endeavoring to have such a tribunal appointed. The members might consist of say, the Mayor, the President of the Art Association, the President of the Royal Academy or some representative of the same, the President of the Association of Architects, and say a representative from the

Government Board of Manufactures or such other bodies as might be arranged. Had such a committee been in existence I feel sure some monuments which have recent y been put up in our city would have been relegated to the limb o of Philistinish things, and we should have been spared many painful sights.

Both New York and Boston go further even than this, however, for in these two cities Municipal Art Societies have been established, with the express object of providing adequate sculptural and pictorial decorations for the public buildings and parks. I understand that the first work done in this way in New York was the decoration of a wall in the new Criminal Court Building, and other work of a similar kind is contemplated. All such efforts are entirely praiseworthy, and the liberality of generous-hearted men might well find an additional channel in the beautifying of our public buildings by painting and sculpture.

Nature has done much for our city, rolling a magnificent river past our doors, and heaving up a beautiful verdure-clad eminence for our habitations to cluster round; let us do our part in making these habitations worthy of their natural surroundings, so that they may be healthy, comfortable and beautiful—worthy dwelling-places of a happy, virtuous and contented people.

These two papers were listened to very attentively and were much appreciated. On the proposition of Mr. W. E. Doran, seconded by Mr. J. Z. Resther, a hearty vote of thanks was accorded the contributors for the papers, after which the meeting adjourned.

THE CONVERSAZIONE.

A delightful conversazione was given in the evening in the galleries of the Art Association to inaugurate the opening of the Exhibition of Architectural Drawings under the auspices of the Province of Quebec Association of Architects. There was a large and fashionable assemblage of people.

Gruenwald's Band discoursed sweet music, and refreshments were served during the evening in the large class room adjoining the gallery. The evening was a thoroughly enjoyable one. This is the first Exhibition of the kind held in Montreal, and has proved more successful than the promoters had ventured to hope for, and may be taken as a favorable augury of what will be accomplished in the future.

The following is a list of the drawings exhibited:

Gordon & Helliwell, Toronto—Church of the Messiah, Toronto; residence of Captain S. Crangle, Toronto; Town Hall and Market, Orillia, Ont. Darling & Curry, Toronto—Church of St. Mary Magdalen, Toronto; Organ of St. James Cathedral, Toronto: Competitive Design for Ontario Legislative Buildings, one large perspective in pen and ink, and two elevations of the same. Frank Darling, Toronto—Head Master's House, Port Hope School, Ont.; house at Niagara; house on College ave., Toronto. W. A. Langton, Toronto—Sketch St. Hilda's College, Toronto. Siddall & Baker, Toronto—Nos. 12 and 14 Colborne street, Toronto (stores); railway station at Janesville; staircase to Music Room, Nordheimer's Building, Toronto; perspective of Competitive Design for Government Buildings, British Columbia. Thos. Fuller, R.C.A., Ottawa—Public Building, Brockville, Ont.; Public Building, Sorel, P. Q.; two views of Public Buildings at Galt, Ont.; design for Superintendent's residence, Experimental Farm, Ottawa; Public Building, Victoria, B.C.; Drill Hall, Toronto; Public Building, Charlottetown, P.E.I. R. Dawson, Toronto—Residence of A. T. Lytle. A. T. Taylor, F.R.I.B.A., Montreal—Interior sketches of house at Ottawa; street scene in Louvain; Hon. Geo. A. Drummond's residence, Montreal; Bank of Toronto, Montreal; Bank of Montreal, west end branch, Montreal; seconded premiated design for Glasgow Municipal Buildings, Scotland; the Engineering Building, McGill College; the Redpath Library, McGill College; interior view Bank of Montreal Head Office; Almhouses, Chiselhurst, England; scene in Perugia, Italy; the Cathedral, Malineo, Belgium; the Physics Building, McGill College; Bank of Montreal, Vancouver, B. C.; Siena Cathedral, Italy: view in Ghent, St. Antonio, Padua. A. C. Hutchison, R.C.A., Montreal—Residence of C. E. L. Porteous, Montreal; residence of W. W. Ogilvie, Rapids Farm; Cote St. Antoine Academy; Erskine Church, Montreal; Young Women's Christian Association Building, Montreal; design for a Bank; Montreal High School; Window, Front Gable Erskine Church, Montreal. Brown & McVicar, Montreal—Residence of F. G. Guadinger, Montreal; residence of George Hyde, Montreal; Taylor's Church, Montreal; Masonic Temple, Montreal. David R. Brown, Montreal—Westminster Church. D. Norman McVicar, Montreal—Tower of Eglise St. Jean, Amiens; Calle off Graod Canal Venice. Miss M. P. Taylor, Edinburgh—St. Giles Cathedral, Edinburgh; Norman Staircase, Canterbury; interior of St. Mark's, Venice. Edward Maxwell, Montreal—Study for residence of H. Vincent Meredith, Montreal; group of three sketches for country houses; view in hall of house for General Manager Bank of Montreal, also exterior view of same; business premises of R. Sharpley & Sons, Montreal; residence for Hugh A. Allan, Montreal; residence of D. McIntyre, Montreal; Competitive Design for Masonic Temple, Montreal. J. W. and E. C. Hopkins, Montreal—Merchants' Bank, Montreal; residence of R. B. Angus, Montreal; business premises of John Murphy & Co., Montreal; North British and Mercantile Insurance Co.'s Building, Montreal; Bank of Montreal, Ottawa; the J. C. Wilson Building, Montreal; Montreal Street Railway Co.'s new building, Montreal. E. C. Hopkins, Montreal—St. Patrick's Cathedral, Dublin. Dunlop & Heriot, Montreal—St. George's Church Tower; houses for Dr. F. W. Campbell, Montreal; proposed residence for Hugh Graham, Montreal. A. F. Dunlop, R.C.A., Montreal—Residence, Edgehill avenue, Montreal; Ice Grotto, Victoria Rink, Montreal; "Dunlop of Dunlop," Ayrshire; St. James Methodist Church. J. C. A. Heriot—Design for a Country House; design for a Country Church; design for a Suburban Residence. Perrault, Mesnard & Venne, Montreal—Church for Pawtucket, U. S. A.; Church of the Sacred Heart; Laval University, Montreal; Banque du Peuple Building, Montreal; perspective of first scheme for Monument National, Montreal; elevation Monument National, Montreal; design for a church. A. Raza, Montreal—St. Bridget School, Montreal; residence for Ald. A. Dubuc, Montreal; residence for Ald. J. Brunet, Montreal. W. McLea Walbank, B.A.S., Montreal; residence for Dr. F. Buller, Montreal; competition design for Masonic Temple, Montreal; competition design for Montreal Board of Trade. R. Findlay, Montreal—Residence of Jas. Morgan, St. Anne de Bellevue; Sun Life Building, Montreal. Roy & Gauthier, Montreal—Competition design for Chicago Court House, U. S. A.; houses St. Louis Square, Montreal; Sacred Heart Church, Ottawa, Ont.; college at St. Thérèze, P. Q. J. R. Rhind, Montreal—Competition design for St. John the Divine Cathedral, New York; competition design for Masonic Temple, Montreal; premiated design for Protestant Orphans' Asylum, Montreal. A. Flockton, Montreal—Residence of L. H. Taylor, Montreal. J. and H. C. Nelson, Montreal—Design for an Educational Institution. J. Rawson Gardiner, Montreal—Design for Business Block; Choir Bolton Abbey; Old Houses, Sussex. Eric Mann, Montreal—Design for an Office Building. A. J. Cooke, St. Lamberts—The Founder's Tomb, St. Bartholemew, Smithfield; design for a Reredos; design for a Font. C. Dufort, Montreal—Design for a Chamber of Commerce. G. A. Monette, Montreal—Design for a Villa Residence. P. B. Williams, Montreal—Design for Memorial Front, St. Michael's Mission, Stepney, London, E. C. L. A. Venne—Design for a Country House; study for stained glass, Head of our Lord, a fragment of window, and design for stained glass and decoration exhibited by Messrs. Castle & Son and Messrs. Spence & Son; also a large cartoon for a window by Castle & Son, and five decorated plaster medels of the Alhambra, which were kindly loaned by Mr. R. B. Angus for exhibition.

On each side of the two doors are beautiful examples of old Chinese wrought iron work, lent by the Hon. Geo. A. Drummond. They are all four floral studies of chrysanthemums and lillies, most interesting and perfect in their design and finish. In the entrance hall two vigorous plaster models are exhibited by Mr. Hall, and in the doorway is hung a beautiful eastern camp sent by Mr. D. A. Watt.

Mr. A. T. Taylor contributed some fine water color sketches of picturesque views and scenes in Italy. Amongst the many beautiful buildings erected in the Romanesque style by this author, the West End Branch of the Bank of Montreal, the Redpath Library and the Bank of Toronto may be mentioned. Another good bit of designing by the same author is his competitive design for the Glasgow Municipal Buildings, of a classical character, and rendered in pen and ink, which was awarded the second premium amongst a large number of competitors. Mr. Edward Maxwell has also some very effective water color sketches, and his study for Mr. H. Vincent Meredith's house is nicely rendered.

Mr. A. C. Hutchison has some good pen and ink drawings—for instance, Mr. C. E. L. Porteous' house—original in conception and good in rendering, as are also his drawings of Erskine Church, his St. Antoine Academy and his house for Mr. Ogilvie.

The design of Mr. J. C. A. Heriot for a suburban residence possesses some merit.

We are glad to see the design of Messrs. Darling & Curry, of Toronto, for the Ontario Legislative Buildings, which ought to have been erected, and would have been an ornament to Toronto, and their perspective of the magnificent Church of St. Mary Magdalene, Toronto.

Mr. J. R. Rhind has an ambitious design submitted in the competition for the St. John's Cathedral, New York, showing an immense deal of labor both in design and draughtsmanship.

Mr. A. F. Dunlop shows a view in pen and ink of St. James Methodist Church, which hardly does justice to the beauty of the original.

Siddall & Baker's design for the Government Buildings at Victoria, B. C., is well shown by a crisp pen and ink perspective.

Mr. Thos. Fuller has enriched the exhibition by a number of small but most daintily rendered water color perspectives of buildings he has designed.

Messrs. Perrault, Mesnard & Venne show a good sepia perspective of their Laval University, Montreal.

Mr. Findlay, amongst other things, shows a very picturesque country house at St. Anne's, and Mr. A. Raza two city residences in the Renaissance style and elaborately decorated.

For the first undertaking of the kind ever attempted in Montreal, the Exhibition is a marked success, and it ought to encourage the Province of Quebec Association of Architects to hold similar exhibitions at regular intervals in the future, which would do so much for the education of the public and the profession at large.

CANADIAN CEMENT, LIME, AND CLAY PRODUCTS.

UNDER the title "The Utility and Value of some Common Mineral," the following interesting particulars were presented in a paper by Mr. A. Blue, at a recent meeting of the Ontario Mining Institute:—

The two most abundant minerals in this country are clay and lime, and they are likewise among the most useful. They furnish the raw material too for mineral industries of the first importance, in which a large amount of capital and many laborers are employed. Yet in the vulgar opinion, clay and lime are not worthy of being called minerals, and the seekers after gold, silver, copper, nickle and iron would scorn to recognize the workers in clay and lime as fellow miners. I think it will not be hard to show, however, that these very common minerals possess a value not in any degree inferior to the metals, and that they are deserving of much greater attention than they have yet received in this country, at the hands of moneyed men, and men of the best technical training in the mineral industries. But let it be premised, that in this paper lime (using the term in its colloquial sense) will be dealt with only as material for the production of cements.

As to the extent and growth of the industries, information is afforded by the census reports of the Dominion Government. But for comparative records we can only go back to 1881; no account was taken of cements in the Censuses preceding the one for that year, and the earlier statistics of the brick industry are of no use in showing its growth.

The statistics of the two industries in Canada and the Province of Ontario respectively, are given in the following table for the years 1880 and 1890:—

	Canada.		Ontario.	
	1880	1890	1881	1890
CEMENT:				
No. establishments	9	19	3	12
Hands employed	115	243	29	128
Wages paid	$38,151	$85,969	$7,000	$39,245
Value of product	91,658	251,175	20,200	153,400
BRICK AND TILE:				
No. establishments	500	627	400	463
Hands employed	4,129	6,737	2,768	3,791
Wages paid	$968,600	$1,428,480	$415,311	$797,257
Value of product	1,541,892	2,684,713	971,158	2,154,152

The noticeable feature in these statistics is the large share Ontario claims in the progress of the ten years. Ten new cement establishments were added, and all but one are credited to Ontario. The number of hands employed by the industry increased by 128, and all but 29 are returned for Ontario works. The amount paid for wages was greater in 1890 than in 1880, by $47,809, and two-thirds of it was earned in Ontario. The increase in the value of product was $159,517, and three-fourths of it belong to Ontario. The progress of our Province in the manufacture of brick and tile was less conspicuous in the decade, although in number of works, employees, wages and value of output, she exceeds all the other provinces combined. In the increase of works from 1880 to 1890, her share was 63 out of 137; of workmen employed it was 1,023 out of 2,608; of wages paid for labor it was $391,946 out of $819,799, and of value of articles produced it was $1,182,994 out of $2,042,821.

But assuming the absolute accuracy of these figures, there is one aspect of them that arrests attention, viz: the relativity of the cost of labor to the value of product in Ontario and the other provinces. For the whole Dominion, in 1880, the ratio of labor to product was 1:2.53, and in 1890 it was 1:2.50 a proportion which every one would be disposed to accept as likely. For Ontario, however, the ratios of labor to product were 1:2.40 and 1:2.70 for the former and latter years respectively, while for the other provinces they were 1:2.95 and 1:2.27. The use of improved machinery would account for this disparity to some extent, although not wholly. So also would fluctuations in the price or the efficiency of labor. The latter cause can be dismissed as improbable, in view of the proximity of the provinces: and while the former might flatter our vanity, it would, in view of all the circumstances, be fatuous to claim for it more than a very modest share of potency in the radical disturbance of ratios. The real cause will probably be found in the different scales of values adopted in different parts of the country, and it is to be regretted that in the Census enumerations account was not taken of quantity as well as of value.

In the statistics collected by the Bureau of Mines last year, the manufacturers of cement in Ontario, gave the value of their product as $127,415, while the number of workmen they employed was 224, and the amount of wages paid for labor $60,208. Their product included 74,353 barrels of natural rock and 31,924 barrels of Portland cement. In 1890 there was no Portland cement made in our province, but the value of cement manufactured that year according to the census was greater than last year by $25,985, while the number of workmen employed was less by 96, and the wages paid for labor less by $20,963. Had we the output for the Census year in quantity, the cause of the discrepancy would more clearly appear. The Bureau's returns of brick and tile for 1893 are also much lower in value than those of the census for 1890, but this is no doubt due to the fact that the financial stringency of last year caused many works to close down early in the season, while others were idle the whole year. The number of men employed was 2,874, the amount paid for wages $531,686, and the value of product $1,339,873—the ratio of labor to product being 1:2.52.

It has been shown that on the basis of values the manufacture of cement in Canada increased from $91,658 in 1880 to $251,175 in 1890. The whole of this product was consumed in the country, but it was far from supplying our needs. In the fiscal year 1880-1 we imported hydraulic, Roman and Portland cements to the value of $53,765, and in 1890-1 to the value of $313,690. But since the fiscal year 1886-7 the Trades Tables, give us the quantity as well as the value of cements imported, and they show that the demand has been largely on the increase.

The following table gives our imports of Portland and Roman cements for each of the seven fiscal years, 1886-93, the great bulk of which was the Portland variety:—

YEAR.	BARRELS.	$
1886-7	102,750	148,054
1887-8	122,402	177,158
1888-9	122,273	179,466
1889-90	192,322	313,572
1890-1	183,728	304,648
1891-2	187,233	281,553
1892-3	229,492	316,179

The total importation in the seven years was 1,140,200 barrels, valued in the Trade Tables at $1,720,570; but to this should be added the $455,445 of customs dues paid to the Government, the costs of freight and insurance and the profits of importers, in reckoning the price paid by the consumers—an aggregate of not less than $3,250,000. In these seven years the increase in quantity was 123 per cent., and in value 115 per cent. But a more striking evidence of the growing demand is afforded by a comparison of the imports of Portland and Roman cements for 1880-81 and 1892-93. In the former year their value was only $45,646, and in the latter it was $316,179, being an increase of nearly 600 per cent. in twelve years. This is a rate that perhaps has not been equalled in any other article of Canadian importation. What is the secret of it, and is the demand likely to be maintained?

The answer to these questions may be summed up in a very significant term of very modern usage on this continent, viz., good roads. The setting in of the era of good roads in this country, as well as in the United States, does not date back ten years, but in that short period much has been learned on the subject, and the street engineer is now as much of a specialist and quite as useful in his way as the military engineer or the mining engineer. The Roman roads of Europe, which have lasted out the traffic of two thousand years, have taught him the invaluable lesson that the only sure way to make a good road is to lay a good and strong foundation. But instead of using stone material, as the Romans did in constructing their great military roads, he has adopted the concrete used by them in the construction of temples and other public buildings, some of whose walls have been standing 2,400 years. The great dome built by Agrippa, the friend of Augustus, "the immortal monument of the Pantheon," as Gibbon described it—now the church of Santa Maria della Rotonda—is an edifice in concrete, and though ravaged by fire and assaulted by the Huns and Goths, it is still intact after more than 1,900 years. Concrete is the street engineer's material for street building, and his chief reliance in the making of it is not Roman or any other kind of natural cement, but the stronger and more durable Portland. In Toronto during the last five years not less than 150,000 barrels of cement have been used in making concrete for street construction, and of this quantity Mr. Rust tells me that not more than 4,000 barrels have been the native hydraulic cement. "Up to the last year or two," he says, "it was all imported Portland cement from Europe." In other towns and cities of the Dominion cement is also being used in steadily increasing quantities in building sewers and streets, and the results are so uniformly good that the material promises to grow steadily in favor. It is almost certain then that for many years yet to come the demand for Portland cement will continue as experience proves the utility and permanency of the concrete roadbed.

But why should we remain dependent on foreign sources of supply for Portland cement? We have in Ontario abundance of raw material for producing it. In scores of localities beds of white shell marl of large extent and excellent quality are found, some of them at the bottom of lakes in which myriads of fresh water shells yet survive, to add to the thickness of the deposit as one generation follows another; others of them on the sites of lakes long ago filled up with peaty mould or drained by continual elevations. This marl, if unmixed with sand, clay, peat, or other matter of mineral or vegetable origin, is almost pure carbonate of lime, and furnishes the principal material for the manufacture of Portland cement. The necessary proportion of clay is a matter of experiment, but in all cases the purer and more uniform the quality of the marl, the easier it is to get a right mixture. Our manufacturers in Ontario have acquired their experience slowly and dearly.

Mr. Rathbun told me that it cost him five years of testing, with the aid of a chemist, before he was convinced that it would be safe to start his works. Mr. Butchart also told me that it cost his company several thousand dollars, a visit to some of the best Portland cement works in England—where he was admitted as a special favor—and the service of two experts in the construction of a suitable plant, before they could produce a commercial article. But the Rathbun Company and the Owen Sound Company have succeeded, and during the last two years they have been producing a Portland cement which satisfies every requirement.

Mr. C. H. Rust, Deputy City Engineer of Toronto, makes this statement concerning it, in a letter which I have just received from him:

"Since 1892 we have used a quantity of Portland cement made by the Rathbun Co., at Napanee Mills, and by the Owen Sound Co., at Shallow Lake. Both these brands are quite equal to the majority of the imported cements, and no doubt, when their facilities for manufacturing are increased nearly all the cement used in this city will be of home manufacture."

The Owen Sound Co., has recently had the misfortune to lose its mill by fire, but it is understood that a new one is in course of erection. The company has a large supply of raw material alongside of the works, suitable clay for mixing being found immediately below the marl, and doubtless the capacity of the new mill will be made to meet the growing requirements of the trade.

The only other Portland cement works in the Province are at Marlbank in the County of Hastings. The site was chosen because of its nearness to a very large deposit of marl; but although English capital was put into the business, and presumably English experience also, the enterprise had to pass through the usual ordeal of disappointment and delay before a successful beginning was made.

The output of those three mills last year was 31,924 barrels, but one of them did not start until late in the season, and another only worked half the year. Had their capacity been six times as great they could hardly have supplied the quantity of Portland cement imported by

Canada during the fiscal year 1892-3, and obviously therefore there is ample room for home manufacture to grow. With raw material so abundant and accessible, and with capital seeking new channels of investment, and labor seeking employment, why should we not produce in the country all the Portland cement that our market requires. An article of uniform quality will always be in request by customers, and with care on the part of the manufacturer there is no reason why he should not be successful in supplying a distinct brand. But as long as we are dependent on foreign makers we cannot hope to be supplied with cement of uniform quality, for where larger orders have to be filled it is a common practice even of large mill owners to buy lots from other manufacturers and so make a prompt shipment. The result is that there are as many brands as makers, and with cements of different qualities, some quick setting and some slow setting, it is hardly possible to make a first-rate concrete. This is a risk which may easily be avoided if orders are placed at home, with the home manufacturer, and the good results obtained from our Ontario cements are no doubt due to the fact that orders are honestly made up, each manufacturer being jealous of his own reputation.

As regards the products of clay, it is not necessary that much should be said. Taking the various articles of common and pressed bricks, terra cotta, tile, sewer pipe, and pottery, the number of men employed in their manufacture in Ontario last year was 3,109, with earnings of $601,686. The aggregate value of their products was $1,684,873, or more than one-fourth of all the mineral products of the Province in the same year. This fact alone suffices to prove the importance of our clay industries; yet it is obvious that they are capable of greater development. The manufacture of pressed brick and terra cotta began here only five years ago, and last year, in spite of the collapse in the building trade, the value of the output of six works was $217,373. It gave employment to 224 workmen, and paid them wages to the amount of $80,686. The improvement already noticeable in the architecture of our cities as a consequence of the use of pressed brick and terra cotta is bringing this material fast into favor, and it may be said that the earth affords no better building material than a properly burnt brick, and none which so readily lends itself to the production of handsome architectural effects. In the strong and fine-textured shales of our Hudson river and Medina formations, conveniently situated and easily quarried, Ontario is favored above most Provinces and States in America.

The same shales are also found to be suitable for the manufacture of sewer pipe, with proper mixtures, and last year the output of two establishments employed in this industry was $230,000.

Another clay industry is now on the eve of commencement, and if successfully established it promises to be a great boon to our towns and cities, viz: the manufacture of vitrified brick for street paving. In Ohio, Illinois, Iowa and other American States, this has grown to be a very important industry, and it is supplying a material for street construction which on all points of merit is not equalled by any other material hitherto employed for the purpose. Many mistakes were committed by the first makers of paving brick, and there is much yet to be learned as to the clays or clay mixtures which give the best results, as well as to the proper degree and duration of heat to produce a hard, tough and impervious brick. But much is already known, and with careful experiments and close observation many works are enabled to produce with regularity a high percentage of paving brick of uniform quality from every charge of a kiln. A number of experiments have recently been made in Toronto, Hamilton and elsewhere in this Province, and although each expert will assure you that he alone knows the secret, and that no one else has the clays for a right mixture but himself, you may rest assured that in a matter of this sort the key and the ward are not so hard to match as the tribe of experts would have you believe. In several instances encouraging progress has been made, especially with the Medina and Hudson River shales.

We may, therefore, I think, look with confidence to an early beginning of the production of paving brick in Ontario; and when that time comes we shall no longer be at the mercy of trust concerns like the owners of Pitch Lake asphalt, as illustrated the other day in the case of a contract for paving in the city of Hamilton. When we are producing Portland cement from our own shell marls and clays to the full extent in which it is required for street concrete, and paving brick from our own shales to cover the concrete, we shall be as independent as we ought to be in supplying ourselves with the materials of such everyday requirements as are called for in the building of good roads. In so doing also, we shall be utilizing our raw materials of clay and lime, otherwise of no value, finding profitable investments for capital lying idle in the banks, and giving employment to hundreds, if not thousands, of men who for lack of work to do are finding it hard to win their daily bread.

With one suggestion to the professors and instructers in the School of Practical Science, Toronto, and the School of Mining, Kingston, I close. Reference has been made to the experiments conducted by the manufacturers of brick and cement, preliminary to the building of works to commence production on a commercial scale. These experiments demand patience, exactness and scientific method, as well as the use of costly appliances. Why should they not be taken up in our technical schools, where there are professors having the necessary expert knowledge and training, and the appliances for making tests and ascertaining results with unerring accuracy? The importance of the clay industry has been so well recognized by the State Legislature of Ohio, that a course of practical and scientific instruction in the art of clay-making and ceramics has been added to the educational work of the state University, and the first term of the department opened yesterday. Work of that character is as much needed in Ontario as in Ohio, and the professors of our scientific schools cannot too soon prepare to enter upon it.

DISCUSSION.

Mr. R. W. Prittie said he had been for a number of years interested in the brick industry, particularly in the manufacture of paving brick. This article was coming largely into use in the States, and he had seen pavements which had been down for 16, 18 and 20 years, with but little repairs. It was giving the utmost satisfaction, and made a superior pavement in every respect, being smooth, lasting, easily cleaned, and affording a good foothold for horses. He was interested in a large vitrified brick factory which had been started at the Humber, near Toronto, last year, and was got partially under way when the financial crash on the other side affected the enterprise and brought it temporarily to a stop. He hoped, however, that the operations would yet be begun. It was the company's intention to put up a plant capable of turning out 50 millions of brick per annum, and employing 400 men.

Dr. A. P. Coleman, in reference to a remark in Mr. Blue's paper, thought it only fair to say on behalf of the School of Practical Science, that they had begun the work of testing cement, brick and similar materials. If provided with proper appliances, the authorities of the School were perfectly willing to engage even more extensively in such work.

Mr. J. Latimer asked if there had been any development in fire clay.

Mr. Blue—Not in Ontario.

Mr. Bell—There are good deposits of fire clay in Nova Scotia, but they are not made use of.

Mr. J. M. Clarke said it was well known that the manufacture of articles like vitrified brick in Ontario had engaged the attention of outsiders more than the people of the province. Outsiders were now investigating the subject with the view of beginning the manufacture of paving brick here.

BEARING POWER OF FOUNDATIONS.

From the valuable note-book of Mr. E. L. Corthell, of the Western Society of Engineers, we have been permitted to extract the following data respecting the bearing power of foundations.

Clay.—From 2 to 8 or 9 tons per square foot, without allowance for friction.

Sand.—The different kinds vary greatly in bearing power. Sand mixed with loam will not bear more than 5 tons per square foot. 9.3 tons per square foot were placed on fine gravel and sand at Urk viaduct; masonry piers on cylinders 4.8 inch diameter; friction neglected.

In India, on coarse sand in deep foundations, not over 9 tons are used.

In experiments 20 tons have been put on sand without measurable settlement.

Friction.—Side friction varies from 300 to 600 pounds per square foot.

All the above are in gross tons = 2,240 pounds.—B. Baker, April 17, 1888.

Clay.—Black Friars Bridge, 5 tons per square foot. Settled badly.—Randall Hunt, Engineering and Building Record, June 23, 1888.

New London Bridge, 5 tons per square foot on piles, = 80 tons per pile. Settled badly.

Newcastle-on-Tyne, 1½ tons per square foot; no settlement.

Fargo, Dakota, four-story building, 2½ tons per square foot; failed. Then 1½ tons per square foot; no settlement.

Cleveland, new viaduct, 1 to 1.7 tons per square foot.

Washington Monument, 9 tons per square foot, inside edge. Clay and sand, 3 tons per square foot, outside edge.

Sand.—Coney Island pier, 5 tons per square foot.

New York Steam Company's chimney, 4 tons per square foot on fine sand settled.

Brooklyn Bridge anchorage, 4 tons per square foot.

Nantes Bridge, 6.8 tons per square foot; settled.

Berlin, considered safe, 2.3 tons per square foot.

Sometimes used to 4.1 tons per square foot.

Albany Capitol, 2 tons per square foot; settled.

Cairo Bridge, fatigue weight:

Channel piers, 3.34 tons per square foot.

River Piers, 33.08 tons per square foot.

Friction on sides taken at 4,000 pounds per square foot; fine sand.

Sioux City, Pier III; sand, 2.04 tons per square foot.

Soft Soil.—India, one ton per square foot used.—Journal of the Association of Engineering Societies.

TO TEST WHITE LEAD.—Those who desire to test in a practical way the merits of white lead will find some useful hints in the instructions issued by an American Association of Master Painters. Substantially it is as follows:—Coat a board primed in ochre with a mixture of one ounce of oil and two ounces of lead. Then put on a second coat over the entire face of board, excepting a small portion in the middle. When this is done, put a third coat over all, excepting another small space, with a mixture also of one ounce of oil and four ounces of lead. Allow one week to elapse between each coat, and paint the boards while in an upright position. The board will, when finished, have been painted as follows: In the middle there will be a narrow space showing ochre priming, and on the left of it another similar space of one coat of lead; on the right of the ochre priming space, as well as on the left of the one coat space, will be similar small spaces, each being covered with two coats, and on the right and left respectively of these will be a larger space, covered with three coats. After the last coat has been on three or four days, place the boards where they will get a southern exposure, and if put over a roof at least two feet above same. If the boards are dry to the touch, they should be placed out of doors for a day or two between coats. The brush should be used to finish the mixing, and the boards should not be sandpapered. The test being one of comparison a separate board must be painted with each of the leads about to be tested. It will not be necessary to use a separate brush for each board if there are so many of them. Benzine is chosen as being more volatile than turpentine to wash out the brushes. Keep the brushes in oil when not in use. The test is intended principally as one of durability, and as after long exposure the covering qualities of the different leads will not be easily determined, they should be noted at the outset.

PLUMBERS' EXAMINATION PAPERS.

THE following are the examination papers used in the Examinations in plumbing by the city and Guilds of London Institute:—

ORDINARY GRADE.

1. (*a*) How would you make a reliable joint between a lead branch and an iron soil-pipe? (*b*) How would you make reliable joints in a stack of iron pipes receiving wastes from baths, sinks and used lavatories, with hot-water supply? (*c*) Describe the cements used for ordinary jointing purposes and their composition.

2. (*a*) Give the composition of ordinary and fine solder, and the melting point of each. (*b*) If a pot of solder is "poisoned," *i.e.* rendered porous or unworkable by the introduction of some foreign substance, how would you remedy it? (*c*) What fluxes are used for jointing copper, brass, lead and iron to lead?

3. Describe the process of autogenous soldering: when should it be used, and what are its advantages?

4. How should sheet lead be set out and cut in order to line a sink 2 feet long by 1 foot wide inside, 12 inches deep at back and sides, and six inches deep in front, with 7lb. lead, turned over on top edges 1½ inches all around? Describe or show by sketch. What would be the total weight of the lead? What would be the total weight of the solder you would use?

5. Show what you consider the best possible arrangement of waste-pipe from a sink, bath or lavatory, with its discharge to drain.

6. Sketch various forms of defective traps with which you are acquainted, and also improved kinds you would recommend in place of same.

7. The well supply to cistern in an old house having permanently failed, it has become necessary to lay on the supply from the town main: what alterations would have to be made in order to efficiently accomplish this?

8. The drain receiving large quantities of waste water from scullery sinks is frequently choked: what remedies would you suggest?

9. Enumerate the common defects found in waterclosets, which are bad in principle and construction, and show by sketch what kind of fittings you would suggest in place of same.

10. Show or describe what you consider the most complete arrangement of waste-pipes and services for a range of three urinal basins with automatic flushing tank over, and proper surface drainage from floors, with the sizes of the various pipes?

11. What precautions would you take in fixing the water pipe (*a*) from a refrigeratnr where food is stored, (*b*) from a sink or lavatory?

12. Sketch a lead bend, elbow and set-off, and enumeraie the various tools required in the formation of same.

HONORS GRADE.

1. What cisterns and pipes would you recommend for the storage and distribution of (*a*) rain-water, (*b*) hard-water, (*c*) sea-water? State your reasons for such selection.

2. Describe the process of manufacture of milled sheet lead and pipe.

3. Show in the accompanying sketch of sectional house, having a water-closet on each floor, bath on first floor, lavatory on ground floor, and sink in basement, the plumbers' work required and the positions you would suggest for the above-mentioned fittings. Describe the form of each fitting you would use, and the size and the arrangements of the various service, soil and waste pipes.

4. Show on the accompanying plan what arrangement you would adopt for a complete system of drainage for the house described above, and give the various sizes of pipes, &c.

5. A water-pipe running alongside a leaking drain receives an injury: describe the circumstances under which sewage can be sucked into the pipe at the point of injury while the pipe is charged with water. A cistern kept charged with water is situated in the roof of a house having three stories. A service pipe from this cistern supplies a bath on the first floor and a bath on the ground floor. Under what circumstances can water in the bath on the first floor be made to discharge through this pipe into the bath on the ground floor?

6. Describe the principles of a common syphon, and state what is the greatest height a syphon will draw water when once set in action.

7. It is impossible to obtain a good fall to a system of house drains: what precautions would you recommend to prevent stoppage? What do you consider the best and also the least fall to be allowed for a 6-inch main drain?

8. Describe or show by sketch what methods you would adopt for ventilating a water-closet apartment which is not placed next external wall, and give your reasons.

9. (*a*) Give some of the causes of "humming" noise in rising mains to cisterns. (*b*) What defects in a system of hot-water circulation will cause noises in the pipes, &c.? (*c*) Give causes of concussion in pipes and their remedies.

10. Describe or show by sketch the "cylinder" system of hot-water circulation and the "tank" system, and give the advantages and disadvantages of each: explain the reason of hot-water circulating in the pipes.

11. Show by plan and section how you would arrange a lead flat, 22 feet by 20 feet, giving size of bays and gutters and formation of approximate weight of the whole?

12. What precautions would you take for the protection of fittings and service-pipes from frost in a country house situated in a very exposed position?

A HOUSE HEATING GAS FURNACE.

At the recent Industrial Exhibition in Toronto, there was exhibited by Mr. A. H. Dixon, of Toronto, a house heating gas furnace, the construction and modus operandi of which are thus described: The furnace has a large fire chamber; the air is admitted to the burners on both sides, through a perforated shield in fine streams over the top of burners. The products of combustion pass from fire chamber into the radiating drum, which entirely surrounds the fire chamber. Between the outer and inner casing of this drum is placed a partition which forms a flue and causes the product of combustion to pass four times around drum before reaching the exit flue to chimney. Besides the large surface of the outer and inner casing or sides of the drum, a series of tubes are placed in the drum, which extend through both top and bottom heads of drum and through the partition forming the winding flue, forming another large heating surface, as the cold air enters into the bottom end of the flues, and comes out heated at the top and passes into the dome of the furnace. The evaporating pan is placed on the top of the fire chamber, connecting to an outside reservoir; in this way the moisture from the inner pan distributes evenly to all the different pipes leading from furnace. The dome of the furnace is provided with an opening and allowing ready access to the water pan.

ENAMELLING CAST IRON.

It is noted as a somewhat singular fact that there are not more than two processes for enamelling cast iron, notwithstanding the amount of ingenious effort put forth in this direction. One of these is the hot process, in which the iron, heated to a vivid heat, is powdered with a flux powder, borosilicate of lead, distributed with a sieve, then heated, and, when the flux fuses, it is powdered afresh with glass more soluble, forming the glaze of the enamel; but this operation is attended with danger, and is not adapted to large articles or for decoration. The second process, which meets the objections named, consists in dressing or coating the article first with magnetic oxide, then dipping it in borosilicate of lead, coloured by metallic oxides, to which is added a little pipeclay, in order to give rather more body. The article thus covered cold, by dipping or with brushes, is put into the furnace, the enamel adhering and vitrifying at the usual furnace temperature used by enamellers, and by putting a coating of coloured enamel with a brush on a first coat simply plain, it is possible to make any decorations desired.

CONCERNING CHIMNEYS.

AMERICANS do not make as much of chimneys as do most of the builders of European countries. The builder is not sufficiently honest about his chimneys. Either he gives them undue prominence, overloads them with decoarted material, or he treats them as though he were afraid of them. The chimneys of Amsterdam are beautiful indeed and add greatly to the picturesqueness of that city. Likewise in Paris, while they are there treated in a way somewhat more decorative than is common to the rest of the world, they are handled in an honest way, no effort being made to conceal them, and their decorative works is that of artists. There is often the idea that the chimney should maintain a symmetrical relation to the rest of the building. However, in no section of the world do we find a high regard for symmetry in chimneys successful; on the contrary, we find the most beautiful chimneys in that part of the world where they are allowed to have largely their own way; coming out of a building in unexpected places and unexpected ways and decorated by the hand of an artist.—The Clay Worker.

A very important conference on the practical setting and workmanship of artisians is likely to arise out of the Building Trades Conference that was held recently at the County Hall, Springgardens, London. It will perhaps be recollected that on the motion of Mr. Gay, chairman of the London Building Trades Federation, it was decided to appoint a committee to consider the whole question of apprenticeship. That committee has carefully considered the matter. A draft has been prepared of the preliminary report, which it is proposed should be discussed at a general conference of all the trade unions and industrial bodies that evince a desire to attend. Among the subjects are the following: To consider the existing opportunities for a boy to obtain a thorough training as a skilled artisian—viz., (a) apprenticeship—its gradual discontinuance and its possible restoration; (b) technical instruction—its proper direction, whether theoretical or practical, the character of the existing classes and their comparative utility, the local distribution of the classes with relation to the needs of the district, the character of the supervision of the existing classes, the restriction of the classes to men actually engaged in the various trades, and the question of assisting the various teaching bodies.

A WILLING WITNESS

TO THE BENEFITS DERIVED FROM ADVERTISING

GEORGE CLATWORTHY.

GENERAL AGENT FOR Willer's Patent Sliding Blinds, AND Wilson's (of New York)

Patent Rolling Blinds
English Venetian Blinds
Rolling Steel Shutters

Telephone No. 1740.

46 Richmond STREET WEST

Toronto, July 6th 1894

C. H. Mortimer Esq
Canadian Architect & Builder
City

Dear Sir,

Being an advertiser in your paper of some years standing, I have much pleasure in testifying to the good results obtained therefrom.

About a year & half ago I ceased to advertise, & business at once declined.

In your issue for June (last month) my adv. again appeared in the Architect & Builder & already as a direct result enquiries are coming in from all quarters & far distant points - from Nova Scotia in the east to British Columbia in the west.

This I think is a pretty good test of the value of your paper to Builders' Supply men, as an advertising medium.

Yours truly
Geo. Clatworthy

A NEW STONE ELEVATOR.

The Engineering and Mining Journal for August 4th describes the Jeffrey stone elevator for the handling of crushed stone, ore, broken coal, and similar materials. An illustration shows the elevator used in connection with a stone crusher, receiving the product directly from the delivery chute of the crusher and discharging it into a revolving screen at the top. The elevator is constructed of two strands of steel chain covered completely with a continuous line of buckets, which prevents the gritty material from coming in contact with the chain and the other principal wearing parts of the machinery, thus greatly increasing its life. The buckets are made of heavy steel with riveted seams, in sizes to suit the capacity. The peculiar shape of these buckets makes it possible to operate the elevator at a very slow speed, at the same time effecting a cleaner discharge than is produced by high-speed machines, to say nothing of the saving of wear and tear. At suitable intervals wrought-iron cross-bars are attached to the chain, carrying rollers at each end, extending outside of the buckets, which support the weight of the chain, bucket, and the material; this causes a roller friction, reducing the strain on the machinery to a minimum and requiring the least possible amount of power.

Here are a few facts about the Chicago Masonic Temple: The frame of the building is of steel bolted together, 4,700 tons of steel having been used. The walls are of stone and pressed brick with marble and bronze trimmings and terra cotta partitions, 2,200 tons of the latter entering into the work. There are eighty-eight miles of electric wiring, and the plate glass would, if laid flat on the ground, cover four acres. The pumping apparatus used in running the battery of fourteen elevators would easily supply water for a city of 60,000 souls. The elevators run at a rate of nine miles an hour and each elevator runs every year 123,136 miles. There are twenty-one stories and on the top floor is an observatory and roof garden.

ARCHITECTS and ENGINEERS
APPLY TO

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc..

THE Royal Institute of British Architects proposes to expend the sum of £200 00 a series of systematic tests of brickwork.

THE project for the erection in Toronto of a first-class hotel, is assuming more tangible shape. The names of responsible gentlemen—one a successful hotel proprietor—are given in connection with the undertaking. Preliminary plans for the building are said to have been prepared, and should financial obstacles not block the way, there appears to be every likelihood that the erection of the building will be proceeded with during the coming year. Toronto is emphatically behind the times in point of first-class hotel accommodation, and there is little doubt that if an hotel embracing every improvement is erected at a cost of a million dollars, as proposed, it will prove to be a paying investment.

BUFF bricks and terra cotta have been used in quite a number of the larger buildings erected within the last year or two, and now under way, in Toronto and Montreal. The appearance of these materials is pleasing in many but not in all instances. The red and brown shades for brick work will probably remain in greatest demand for all classes of work. The lighter colors have some advantages in certain positions, but never give the effect of strength and solidity that the darker shades do. Among their disadvantages may be mentioned their greater susceptibility to injury by smoke and dust. They can always be used with good results for trimmings and in combination with other shades, but their suitability in large masses depends largely on the surroundings of the proposed structure.

CONTRACTORS for masonry or brickwork should give as much attention as possible to the various uses of concrete and cement work, for which there is an increasing demand. These materials will undoubtedly continue to grow in favor, and the contractors who are best prepared to handle such work intelligently will most uniformly obtain good results, and reap a corresponding benefit. The proper use of cement requires far more care than ordinary mortar, and with it a contractor has more risk of loss through bad material or inexperienced workmen. In fact, the better kinds of concrete work should only be placed in the hands of the most skilled artisans. Concrete well finished in cement is the ideal cellar floor for dwellings, and its adoption for this purpose will be greatly increased as the importance of making houses moisture-proof becomes better understood. Laid in a similar manner, it is a favorite material for first-class sidewalks, and is unequalled for making a suitable road-bed for any kind of pavement. For foundations it is indispensable, while its value for fireproofing, and its adaptability to many other purposes in building are only beginning to be understood. In no kind of work should a contractor be more particular as to the quality of his materials. Whether using native or imported cement, he should be sure that it is in good condition, and not try to do work with any less than the quantity necessary for a thoroughly good job, but rather insure perfectly satisfactory results by allowing a margin on the side of strength. In our next issue we shall publish a number of carefully selected standard formulas for mixing concrete and cements.

THERE is a suggestion for wide-awake manufacturers and dealers in building supplies in the advertisement of an architect which appears in this number, inviting information concerning such materials. The cheapest and most effective method of affording information of this character to architects is by means of a standing announcement in the pages of the ARCHITECT AND BUILDER, which will be found on file for reference in the offices of 90 per cent. of the architects of the Dominion.

SOME recent remarks of Judge Ferguson, at Ottawa, in regard to the terms of a certain contract being very hard on the contractor, have attracted considerable attention from the local contractors, some of whom say that they do not get fair treatment as contracts are at present made out. While admitting that the various stipulations are intended to act as a preventative against fraudulent contractors, they claim that there are clauses not needed even for this purpose. We have long been of the opinion that the usual form of building contract would furnish good material for the careful consideration of contractors, with a view to securing some changes. One clause only will be cited here, viz., "That in the case of several contractors being employed on the work, no trade is to be considered complete till the other several contracts are also completed." Contractors are every day signing conditions which, if rigidly enforced, would compel them to perform work as part of the contract without having had adequate opportunity of estimating its cost. Other conditions might in various ways be made burdensome to contractors. To the credit of the architects it can be said that their large powers are seldom abused, but there is a difference between them in this respect, which is properly taken into account by contractors in tendering. It is hardly fair to ask contractors to sign articles of such a nature as can only be required as a general protection from unreliable persons. Owners are encouraged to believe that with such ironclad conditions the architect is sufficiently armed to insure a first-class job from any one regardless of price. Contractors would be justified in objecting to such clauses. The architect is supposed to stand as the independent interpreter of the obligations between proprietor and contractor, but since he is in the pay of the proprietor it is only reasonable to expect that he will be more particularly interested on the side from which he receives his commission. It follows that the contractor must look after his own welfare, and the clearer and more definite contracts can be made the more satisfactory will be his position and the less embarrassing that of the architect. We believe the architects would gladly meet the contractors for the consideration of questions of this kind. We have no hesitation in saying that the Uniform Contract used in the States and approved by the American Institute of Architects and the National Association of Builders, is better than the forms in use here, but it also is capable of being improved.

THE annual convention of the American Institute of Architects held in New York last month is likely to have a marked influence towards bringing about some changes in practice. Many valuable papers were read; some of these called out spirited and interesting discussion. The president's address contained brief references to the past year's experience and suggested lines of discussion for the Institute to take up. We quote only a few sentences as follows:—"There is great virtue in the formal publication of any truth."—"It is a good thing for the Institute to publicly express its views concerning vital matters of professional conduct." "Whatever the Institute condemns the architects must conform to, and stand squarely on its decision, or lose caste in the eyes of the profession and of the public."—In the discussion on his address, the president recommended that the Institute especially express its views regarding the practice of doing work without proper remuneration, either in competition or otherwise, and that such practice be stamped as unprofessional. If this was published as the view of the Institute, it would have great weight, while the same belief expressed by the members to each other privately would have no influence whatever. The report of the Committee on Competitions was approved and the committee continued to prepare a code embracing the views expressed in the report. It is not proposed to make any change in the rate of 5 per cent. on the cost of the work for full professional services, including supervision, 3½ per cent. for preliminary studies, general drawings, specifications and details, and 2½ per cent. for the same, less details. A radical change is proposed, however, in charges for preliminary studies, as follows:—

Minimum charge $50.00.

For works costing	$ 5,000 to	$ 50,000,	1 per cent. of proposed cost.
" " "	50,000 "	75,000,	$ 550.00
" " "	75,000 "	100,000,	650.00
" " "	100,000 "	150,000,	750.00
" " "	150,000 "	200,000,	950.00
" " "	200,000 "	250,000,	1100.00
" " "	250,000 "	300,000,	1250.00
" " "	300,000 "	350,000,	1350.00
" " "	350,000 "	400,000,	1450.00
" " "	400,000 "	450,000,	1550.00
" " "	450,000 "	500,000,	1650.00
" " "	500,000 "	600,000,	1750.00
" " "	600,000 "	700,000,	1900.00
" " "	700,000 "	800,000,	2000.00
" " "	800,000 "	900,000,	2200.00
" " "	900,000 "	1,000,000,	2350.00
" " "	1,000,000 "	1,250,000,	2500.00
" " "	1,250,000 "	1,500,000,	2850 00
" " "	1,500,000 "	1,750,000,	3050.00
" " "	1,750,000 "	2,000,000,	3300.00
" " "	2,000,000 "	2,500,000,	3500.00
" " "	2,500,000 "	3,000,000,	3950.00
" " "	3,000,000 "	4,000,000,	4300.00
" " "	4,000,000 "	5,000,000,	5000.00

The rate is about 2½ times the square root of the lowest estimated cost. This rate seems excessive for inexpensive buildings, but is about right for buildings of great cost. It is expected that architects will not enter competitions unless paid for their services according to the above schedule, and it is hoped to discourage competitions for buildings of low cost. The table of charges quoted is to supersede the former rate of 1 per cent. on estimated cost for preliminary studies. Competitions are not to be entered into except for public buildings, and then only on condition that four competitors shall be paid at the schedule rates, and one employed as architect with compensation at the minimum rates fixed by the Institute. The paper on High Buildings brought out in discussion a variety of opinions regarding the durability of iron skeleton construction. In a paper read on fireproofing it is assumed that if protected from fire such buildings are practically indestructible. Mr. Post, who has had a large experience in erecting this kind of buildings believes their life will be but short. His opinion, supported by others, is, that the most serious drawback is the effect of rust on the iron. In view of this he argued in favor of cast iron for columns instead of wrought iron or steel. These ideas were strongly opposed, but the conclusion is unavoidable that every possible precaution should be taken to protect iron work from rust in whatever position it may be placed, and also as far as possible to arrange the construction so that it can be examined and painted from time to time. A paper on elevators treated exhaustively of the mechanism of the modern electric elevator, showing its advantages over other kinds. The opinion is expressed that little improvement in these appliances is to be looked for in the near future, for the reason that in every industrial development there are forms of machines which early become typical and remain so, and that machines are now in use of so high efficiency as to leave little margin for improvement.

Some experiments were recently made by the Buildings Inspection Department, Vienna, on the protection of iron from fire by incasing it with brick. A wrought iron column, 12 feet long, and built up of channels connected by lattice bars, was used. This was set up in a small chamber constructed of brick, and the column was loaded by levers. This done it was surrounded by a 4½ in. brick wall laid in fireclay mortar. Between the wall were fixed samples of fusible metals, which should serve as a gauge of the temperature attained. Various samples of stone concrete and other materials were also placed in the chamber within the column. This chamber was then filled with firewood, which was lighted, and the doors were walled up. An examination of the room after the fire had burned itself out showed that the walls of brick laid in Portland cement retained their strength whilst most of the natural stones left in the chamber had been destroyed. The ceiling had been lined partly with plaster of Paris and partly with terra-cotta tiles. Both were damaged. The inclosure round the iron pillars was still standing firm, though corners of the brick-work were chipped 1 in. or so, and the fireclay mortar was largely washed out of the joints. On removing the casing, however, the pillar inside was found to be uninjured, even the paint being unscorched, and the fusible plugs only showed a temperature of 149 degs. Fahr.

THE BYSTANDER.

THE social element in human nature goes a long way to smooth down the rough places everyone meets in his path-way in life; and when this feature of character is found wanting in man, either individually or collectively, the circumstance is likely to produce comment. The Bystander heard the charge made a short time since that the architects of this city were an exclusive and unsociable body of men. "There could be no doubt, but that they were a fine class of men," said a member of the profession, "and when assembled in their annual gathering, they are hail fellows well met, and an enjoyable, as well as a profitable, time can always be spent in their company. When, however, they get outside of the walls of their association meetings, they are as unsociable as members of some of our religious bodies, when disassociated from the organized body, or on the ordinary six days of the week." The complaint of this friend was that each one seemed to be so taken up with his own personal affairs, no opportunity was given to cultivate that spirit of cordiality that ought to exist, he believed, among any class of people engaged in the same calling. The Bystander has always held that not alone is it an agreeable thing for men in the same business to get together occasionally, but that it is a very profitable matter. Our ideas are broadened as we rub shoulders with one another. The suggestion was made, as one means at the present time of bringing the brethern together and helping to break down this barrier of exclusiveness, that the drawings that had been sent for exhibition at the Quebec Association by the Toronto architects, should be placed on exhibition at some central point in the city, where each could learn what the other had done on this occasion, and thus meet, exchange views and become better acquainted. On this matter of personal sociability, the Bystander thinks of a remark made by Henry Ward Beecher, that people sometimes charge others with being unsociable, when they themselves are the real source of the trouble. He said, "I have known persons to cross to the opposite side of the street, when seeing an acquaintance coming along, having the notion that he would not care to speak to him, where the real fact is the individual in question only wanted the opportunity to cultivate a better acquaintance."

× × × ×

An old saw that finds many illustrations in everyday life is that which tells that extremes meet. Human nature seems born to run to excess, for no sooner is the folly or the excess of yesterday learned, than to day the di position is to go to the opposite extreme. Only a few years ago, and a year is a short period in the history of a country, times were flush almost the world over, and little importance was placed on the out-go by any class of people. Reaction came, as it had come before, and as it will come again, and multitudes struck hard bottom. To-day there is seen, as a result of this change, the extreme of the prodigate age, and "cheap," and "squeeze" is the policy of the day. Everybody sees this kind of thing in the ordinary commercial transactions of life. The Bystander has been impressed with the fact that this prevailing spirit of hard times has few, if any, limitations. How it crops out in the matter of building contracts. No value would seem to be placed by many on their own individual time or labor, or that of their employees. Chatting the other day with a city architect, he said: "Let me show you what encouragement there is to embark in contracting and building in these times. Here are the drawings for a house that I figured down to $5,000, without heating, which added would represent several hundred dollars extra. Now in my judgment this figure could not possibly stand any paring, and even allow a living wage to the contractor and the opportunity to pay his men the current wage of the day. What is the situation? I have just now let that contract to a man in this city who agrees to construct the house according to plans and complete it with heating, all for $4,800." How is he going to manage it? was a natural question to ask. "It is just like this in his case," said the informant. "This man is a mechanic himself; within his family are bricklayers and stone masons. They will keep the work largely within their own hands. None of them can make so much as a journeyman's wages, but work is slack and they are glad to get anything to do and accept any price." From one point of view this seems a common sense method to adopt. Better half a loaf than none. It is a method, however, that may someday serve as a boomerang. Many workmen who are not situated as the parties who took this contract and able to work together, are tied down to the regulations of their trades unions, and they must walk the streets day in and day out. The Bystander is informed that with certain trades the carrying on of work during the depression of the past few years has been absolutely blocked because of the determined attitude assumed by workingmen in the matter of wages. And yet the winter approaches and those who would not deviate 25c a day from the standard wage, when capital has been earning its smallest interest, would accept a half wage for a day or two at the city's expense to toss snowballs in the air. Of such it may well be said, with Milton: "They feel by turns the bitter change of fierce experience."

× × × ×

A pleasant hour was spent by the Bystander a short time since in the studio of Mr. J. W. L. Forster, the well-known and talented portrait-painter of this city, whose portraits of Mayor Kennedy and other prominent citizens have from time to time elicited many encomiums. Excelling in his own special line of art he is also able to take a long view of artistic affairs. He sees a close relationship between the work of an artist, using the term in its usually accepted sense, and that of the architect. Both, in fact, are artists, and Mr. Forster expressed the view that each might learn something from the other by an occasional interchange of opinions. The conversation getting down to something specific, a discussion followed touching the matter of interior decorations. The view was expressed by this artist that the artistic effect of a room might be largely enhanced, if the plan were adopted of darkening the lower part of the windows and allowing the natural light from the heavens above to pour into the room, rather than the imperfect light there comes through a window as now constructed. And suiting the action to the word he illustrated what he meant by darkening his own window at the lower part, closing out the light in that manner, but allowing it to come in from above. "Now," said he, "observe the softening effect on everything in the room, the carpets, the furniture, and even the clothes that one may wear." How would it answer to arrange for a social gathering some evening of the artists and architects of the city?

× × × ×

Everyone has not the courage to speak out in meeting, but were it not for some brave mortal doing this occasionally, things could come easily to a standstill in some of our best regulated organizations. A letter in the October CANADIAN ARCHITECT AND BUILDER proding the Executive of the Ontario Association of Architects is a case in point. The Bystander has learned that some of the profession do not take kindly to the criticism. This, however, is not the unanimous view. It is held by not a few leading architects that the Ontario Association of Architects could show an increased measure of activity, and then not over-exert itself. It is to be remembered that the annual meeting is near by, and yet very little has been done to secure a successful and profitable gathering. Aside from this, members of the profession say to the Bystander, why should we exist only for the sake of getting together once a year? Other associations map out programme enough to keep themselves fairly in the front the year through. Furthermore, whilst a large number of the members of the Association are residents of Toronto, yet a number are outside of the city, and they would like to know occasionally what the Executive is thinking about. The letter of "City Member" is believed to have more truth than poetry in it. At the same time, a member of the Executive has said: "Let this writer reveal himself and we will give him the opportunity to show his activity." Others are wont to quote Byron, and say:

> Seek roses in December; ice in June;
> Hope constancy in wind, or corn in chaff;
> Believe a woman, or an epitaph,
> Or any other thing that's false, before
> You trust in critics.

× × × ×

There recently visited this city the correspondent of an American lumber journal, and in a published letter, he made this statement: "I found at Toronto, and the same is presumably more or less true of other border cities on the Canadian side, that considerable yellow pine timber and joist was being used in the construction of public and other large buildings. Some of these are

alter plans drawn by American architects, who appreciating the superiority of yellow pine as bearing joist specify that kind of stuff." Those who have interested themselves in lumber matters are aware that an effort has been made to create a market in the eastern states for the yellow pine of the south, and bring it into competition with white pine, a large part of which now goes to these states from Canada. To only a small extent, however, has this wood been successful as a rival to white pine, except for some common uses, where price was a consideration. Knowing these conditions it seems clear to the Bystander that yellow pine, when used in Canada, has not found any large place here on its merits, but simply, as this American journal has suggested, because American architects have designed plans for the buildings where such pine is used, and have not lost an opportunity to promote the interests of a wood grown in their own country. The injustice to Canada of giving the work of designing public buildings to foreign architects does not, therefore, come home only to the Canadian architect, but as it seems here to other interests in the country as well. It would be taking a narrow view of conditions to say that the interests of any concern, or of the public, should be sacrificed by refusing to place in outside hands work that could not be done at home. But with the high standing of the profession in Canada, and their work is before everyone to testify to the fact, is it not disloyalty to our country and people to seek talent abroad for the designing of any of our buildings, public or private?

× × × ×

Looking around the other day among the new buildings in the business part of Toronto the Bystander met Mr. Henry Langley, of Langley & Langley, in the store of John Catto & Co., which is being constructed under his direction. Mr. Langley was engaged just then in inspecting a case of terra cotta brick. Architects and builders have evinced more than average interest in the terra cotta used in the construction of the Catto building. It is made by the Rathbun Co. Taking a cursory glance at the front of the building one might notice that it bears an embossed appearance. The bricks are combed, Mr. Langley says, and afterwards cut to proper size, giving a very tasty effect. The Bystander had heard some complaint of the quality of this terra cotta. "The trouble has been," said Mr. Langley, "things were rushed too much at the outset, and the plant of the Rathban Co. overtaxed. As a result some of the terra cotta was not burned sufficiently." A feature of the bricks which attracts attention is the small oblong shape. So far no large quantity has been used in building construction in Toronto. In Buffalo and other American cities this brick is used largely, the first lot, it is said, being imported from Scotland. Its introduction here may be taken, perhaps, as a movement to get away from the staid routine that is often a serious fault in the construction of buildings, both for public and private purposes, in all our cities.

× × × ×

The work of brick-making in Canada has grown apace since the early inhabitants of Babylonia found on the plain in the land of Shinar clay for their construction, and "said one to another, Go to, let us make brick and burn them thoroughly, and they had brick for stone and slime had they for mortar." The reference in another paragraph to the class of brick that has been used in the construction of the new store of John Catto & Co., is an illustration of Canadian progress in brick-making. Said Secretary Phillips, of the Builders' Exchange, a few days since: "Really commendable and substantial progress in brick-making has been made in Canada within the past few years. One does not need to go far back in memory to talk of bricks at $40 a thousand. To-day we are getting a good pressed brick for $16. Brick-making has become a very thorough study with some of our manufacturers. I do not know just what amount of money, for example, Taylor Bros. have expended in experiments in order to reach the high degree of perfection that is shown in their pressed bricks, but the sum has been considerable. And what has occurred with them has had a parallel, in a measure, with the Rathbun Co. and other manufacturers. Despite a duty of 25 % Canadian brick-makers have been able to send into the United States large quantities of their bricks." Methought these were complimentary words for Canadian brick-makers. They furnish proof that thoroughness and a determination to reach as nearly to perfection as possible are elements certain to achieve success. Brick making is an industry full of large possibilities. The Bystander has been asked as to the resisting power of fire bricks. An authority on the question says that fire bricks will resist a crushing force of from 600 up to 3,000 pounds per square inch.

AN INTERESTING ARBITRATION.

An important arbitration has recently been concluded between the corporation of the City of Moncton, N. B., and the Moncton Gas, Light and Water Co., to determine the amount which the city should pay the company, in consideration of the transfer of the company's property to the corporation.

In 1878, the company were given a charter by the provincial government to construct works and supply water and light to the city, on such terms as could be agreed upon between the company and city, for a period of ten years. The necessary works were constructed, Mr. E. H. Keating, the present City Engineer of Toronto, and the late Mr. Gilbert Murdoch, of St. John, acting as consulting engineers on the work. The works were extended from time to time afterwards, an electric lighting plant being added in 1888. Terms were agreed upon between the city and the company, and after the expiration of ten years, the period of the contract, a renewal contract for a further period of five years was arranged. This renewal contract expired in the early part of 1893. Dissatisfaction was expressed by the city with the character of the service performed by the company under the contract, in consequence of which the city announced its intention to own and operate its own water and light plant, and made an offer of $180,000 for the company's property. This offer being declined, the city made application to the legislature for a special act to authorize them to construct the necessary works for the supply of water and light. This application the legislature refused, but as a compromise, authorized the expropriation of the existing works at a price to be fixed by arbitration.

Mr. Robt. Surtees, City Engineer of Ottawa, was chosen as arbitrator on behalf of the city, Mr. Walter Shanly, C. E., of Montreal, for the company; Mr. F. T. Holt, C. E., of St. Stephen, N. B., being appointed by the Lieutenant-Governor-in-Council, as third arbitrator. The legal counsel for the city were: B. M. Britton, Kingston, Ont., Hon. H. R. Emerson, Commissioner of Public Works, H. A. Powell, M.P.P. and Mr. B. Chandler, of New Brunswick. The company were represented by Hon. A. G. Blair, Attorney-General of the province, A. A. Stockton, M.P.P., C. W. Weldon, Q.C., R. A. Borden. The engineering expert for the city was Mr. Willis Chipman, of Toronto, who was assisted by Mr. John McCready, City Engineer, and Mr. J. J. Taylor, of Moncton. For the company M. M. Tidd, C. E., of Boston, Mass., their permanent engineer, John Edington, and Mr. Croasdale, of Moncton.

The arbitration opened the latter part of August. The taking of evidence occupied three weeks. The case hinged largely upon the interpretation of a single word. The Act under which the arbitration was held, declared that "The arbitrators shall proceed to determine the compensation to be paid." The important word was "compensation." The company claimed that the compensation should be based on the net earning power of the plant, capitalized at 4 per cent., with an allowance for prospective profits for the next ten years. The average net earnings of the company for the last six years were shown to have been $24,000 per year, and calculated on this basis, the valuation placed upon the property by the company was $800,000. The company's construction account showed amount expended to have been $281,000. The total cash paid for stock was shown to have been $116,000; stock paid out of earnings was $100,000; making total stock issue $216,000, to which must be added $60,000 bonds.

The city contended that they should not pay more for the works than would be required to construct new works, less depreciation. Mr. Chipman estimated the cost of new works at: $137,500 for water works and $74,000 for lighting a total of $211,500. This estimate did not include some lands of the company, on certain streams not in use, which would bring the total up to $225,000. The depreciation was estimated at $17,500, which deducted, left the total estimate $208,000.

The award of the arbitrators, which is signed by Messrs. Surtees and Holt only, gives the company $265,000 for the water works, and $78,000 for the lighting system a total of $343,000.

The water committee of the City Council, in their report on the case, bestow credit on the legal counsel, and on Mr. Chipman, the engineering expert, for the ability with which they handled the city's case.

ELECTRIC PERCUSSION AND ROTARY DRILLS.

The accompanying illustration shows in operation at the Windsor Gypsum Quarries, Windsor, Nova Scotia, portable electric percussion and rotary drills which have lately been introduced and are being manufactured by the Canadian General Electric Co.

The percussion drill in general external appearance conforms very closely to the regular type of steam and air drill; in fact, the tripod and shelf are of the standard steam drill form. Electrically, it is arranged in the form of a solid piston reciprocating in a magnetic field and controlled thereby. The piston is provided with a standard air drill rotating rifle-bar and the usual form of springs to protect the front head of the drill from blows. The drill has a piston diameter of 3¼", a length of stroke from 6½" to 8½", length of feed 24", number of blows per minute, 360 to 380.

The first of these drills was installed on the Canadian "Soo" Canal last winter, when the contractors, Messrs. Hugh Ryan & Co., were greatly pleased with its performance. On these works the performance was equal to that of a 3" steam drill, and the facility with which the drill could be moved, owing to the complete flexibility of the connections, was especially remarked. As far as economy goes, it far surpassed any other drills on the works. The cost of operating, including power for operating the generator and labor of the attendant at the power house, was somewhat under the average operating expenses of the steam drills. Bearing in mind that the attendance at the power house is the same whether one drill or fifty are in operation, and that the increase of power is by no means in proportion to the number of drills, it will be readily seen that a very great saving will be effected over steam drills where the number in operation is the same.

ELECTRIC PERCUSSION AND ROTARY DRILLS, IN OPERATION AT THE WINDSOR GYPSUM CO.'S QUARRIES, WINDSOR, N. S.

In the Windsor Gypsum Quarries, Windsor, N. S., where one of these drills is in operation, every satisfaction is being given by it. The best day's work of one drill on record is ten 10 ft holes in 9 hours and 20 minutes. This was in glow lime stone.

The rotary drill is designed especially for use in coal mining but has also been used with great success in the Gypsum Quarries of the Windsor Gypsum Co., where the clayey nature of the material tends to clog the drill and imposes the severest test on the capability of the machine. The drill is similar to the well-known Howell's drill with an electric motor geared to it in such a way as to form a light and efficient tool. The control of the motor is effected by a small plug switch. No rheostat being used, power may be taken from the same wire supplying current for lighting, pumping or haulage.

Feed screws of different pitch are furnished for varying the speed of boring and a friction clutch protects the motor should any particularly hard obstacles be struck suddenly.

The columns are made in different lengths and each is adjustable for about two feet variation. The construction of the drill and its method of mounting enable the operator to drill close to the roof, floors or walls as well as in any direction.

The drill weighs with post complete only about 160 lbs., the drill itself weighing 100 lbs. In bituminous coal this drill shows a speed of drilling of 7 to 10 feet per minute.

COLLAPSE OF BUILDINGS.

The records of failures in the Middle Ages rather indulge in religious than in practical explanations of the causes, and so, says the Builders' Reporter, we do not gain much practical knowledge from these examples, such as the fall of the towers of Winchester Cathedral in the twelfth century; of Glouchester Cathedral, in 1160; of Worcester Cathedral, in 1175; of Evesham, in 1215; of Dunstable Priory, in 1221; the smaller towers of Worcester Cathedral, in 1222; the tower of Lincoln, in 1244; of Ely Cathedral, in 1322; of Norwich Cathedral, in 1361; and the west front of Hereford Cathedral, in 1786; the central tower of Hereford would have fallen had not its impending ruin been observed and remedied. The old tower of Thurston Church, Suffolk, fell in 1860. Then we have the Chichester tower in 1861. The above small list of towers awakens the thought that special care is needed for all structures that are carried upon piers instead of upon continuous walls. But the description that has been given of the cause of failure in the Chichester tower would have been very applicable to many of the other cases. The lesson derived from the Chichester fall seems to be that rubble masonry should never be used in piers carrying towers or other heavy work; it is a masonry suitable where bulk and weight are main objects, but it is inadmissable where unyielding vigour of pier is to be attained; it also suggests that in any such case a soft kind of stone is scarcely safe even if it be of a sound nature; and the stone forming the facing at Chichester, though in some respects a good stone, was not suitable where a crushing force was the chief force in action. It was from near Binstead, in the Isle of Wight, and it is the only tertiary building stone in England; but if we want a thoroughly good freestone we must get it out of the secondary beds. The stone in the piers of the French Panthéon was of a rather weak quality, but that with which the inner and intermediate domes were formed was tertiary, from the quarries of Conflans, about eighteen miles from Paris, and for which latter purpose it is particularly suitable.

PERSONAL.

Mr. E. L. Horwood, architect, Ottawa, through our advertisement columns, invites manufacturers to send him copies of their catalogues.

Mr. E. B. Merrill, who was for many years instructor in electricity at the Toronto Technical School, has been elected principal of that flourishing institution.

Mr. William Robinson, who for 21 years occupied the position of City Engineer of London, Ont., died in that city on the 10th of October. Mr. Robinson at one time practiced as an architect and land surveyor in Toronto.

In considering simply the proper and best use of color for house interiors it is not necessary to include the question of ornament or elaboration either of walls or ceiling. These may follow, but tint must go before, and if thoroughly studied and well chosen, can very well dispense with ornament.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

THE MASTER PLUMBERS' ASSOCIATION.

The recently formed Montreal Master Plumbers' Association will apply to the legislature for an act of incorporation. As the result of correspondence which has been going on for some time between the Association and some of the leading plumbers of Quebec, it is probable that a plumbers' association will be organized at an early date in that city. The Council of the Arts and Manufactures Association has invited the Association here to assume superintendence of the plumbing class in connection with that institution. The meetings of the Association, which thus far have been held regularly twice a month, are well attended. Careful consideration has been given to the city plumbing by-law. The endeavor will be made to bring about a conference at an early date of representatives of the Association and of the City Council, to discuss needed amendments to the ordinance.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

At a recent meeting of the Council of the Province of Quebec Association of Architects it was decided to hold monthly meetings and dinners of the members of the Association on the second Tuesday of each month during the winter, in the rooms of the Association, New York Life Building. It was also decided to hold a general special meeting of the members of the Association on Thursday, December the 6th, at 4 o'clock p.m., to discuss the amendments to the by-laws which will be proposed according to the notices of motion given at the last annual meeting, as follows:—Mr. A. C. Hutchison will move to make the following change in section XI of the by-laws: to strike out the following words in the 3rd, 4th and 5th lines of the section—"to collect all funds and hand them to the Treasurer, taking his receipt for the same;" and in line 8 of the same section to omit the words—"receipt for them to the Secretary," and to add to section XI the words—"The Treasurer shall also furnish to the Secretary at the close of each year a list of the members whose subscriptions have been paid.

Mr. W. E. Doran will move to amend section V of the by-laws by changing the words in sub-section III thereof, after "separately," to read as follows—"The retiring President shall be ex-officio the premier member of the Council, the other five members to be balloted for on one paper."

Mr. Victor Roy will move that "The Lieutenant Governor of the Province, the Prime Minister, and the Minister of Public Works of the Province, the Mayors of Montreal and Quebec, the Honorable Sir Donald Smith and G. A. Drummond be elected as honorary members of our Association."

Mr. A. T. Taylor will move "That the Council shall appoint a Board of Examiners composed of six members, instead of four, as in the past."

Members of the Association who may desire to introduce any sub-amendments in connection with these amendments, are requested to communicate them in writing to the Secretary on or before the 17th inst.

Mr. A. F. Dunlop, who was elected a member of the Council of the Province of Quebec Association of Architects at the recent annual meeting, has since resigned the position.

THE BUILDING BY LAWS.

There are probably on this continent very few cities of the size of Montreal where the aesthetic in architecture is so much ignored. Some of our city fathers even are not more enlightened on the subject than their electors are. An example of the extent of their knowledge in that line was the passing of a by-law a few years ago, when the street railway craze began, to the effect that all buildings erected in future on the new street line should be faced with stone and be not less than three clear stories in height. As the result buildings strictly in accordance with this by-law, but of cheap construction and mostly of poor design, sprung up on these promising thoroughfares, of which Notre Dame street is a recent example. Brick and terra cotta of any kind were absolutely prohibited for the facing of front walls. These materials in the eyes of some of our aldermen are merely baked mud unfit for decorative purposes, but such highly ornamental and substantial material as galvanized iron was allowed to be used in profusion for decoration and the construction of cornices and towers. Recently the Merchants' Bank of Halifax, which is erecting a very creditable and ornamental building at the corner of Seigneurs and Notre Dame streets, asked permission of the City Council to use buff pressed brick on the Notre Dame street fronts After considerable opposition on the part of some of the aldermen the by-law was amended, and anyone may now use pressed brick for facing front walls. When that by-law was passed, instead of prohibiting the use of brick, which they thought was too common a material to be used on those streets, the aldermen might better have directed their attention to forbidding the employment of galvanized iron for cornices, etc., as a substitute for terra cotta and stone, and to the regulation of the height of each story, so as to ensure uniform height in the buildings, thereby preventing such erections as that on the corner of Notre Dame and McGill streets, one of the best business locations in the city, where the building conforms in every way to the by-laws, with a stone front, and three stories in height, but where the height of each story is not more than seven feet six inches. Would it not be wise for the civic authorities when a building permit is applied for not only to enquire about the constructive merit of the structure but also as to its artistic merit, with the object of putting a stop to the erection of buildings from so-called "builders' designs," and the showy and ill-constructed buildings put up wholesale by speculators, which at present do so much to disfigure our streets?

COUNCIL OF ARTS AND MANUFACTURES OF THE PROVINCE OF QUEBEC.

The schools of the Council of Arts and Manufactures of the Province of Quebec are institutions which interest in the highest degree architectural students, and apprentices devoted to the building arts in general, as they afford to pupils great facilities for developing their talents and taste in branches of study which are seldom met with in the daily routine of the office of the architect or in the workshops. These schools are established in all the cities of importance throughout the province, as in Quebec, Levis, Three Rivers, Sorel, Huntingdon, Granby, Sherbrooke, St. Hyacinthe, St. Jerome, and Montreal, which is their headquarters. The first schools, that is those of Montreal and Quebec, were founded in 1873 by the Provincial Government, which elected a board of management actually composed of Messrs. E. E. Paché, J. F. Peachy, G. E. Tanguay and Rev. J. C. K. Laflamme, of Quebec, T. Normand, M.P.P., of Three Rivers, D. Lainé, of Levis, A. G. Lomas, of Sherbrooke, Paul Payan, of St. Hyacinthe, L. I. Boivin, G. Boivin, A. Boyd, Victor Roy, J. McFarlane, J. D. Rolland, F. J. Hart, J. C. Wilson, and W. McMaster, of Montreal, and S. C. Stevenson, B.A., as Secretary.

As a representative of the CANADIAN ARCHITECT AND BUILDER, I had the opportunity of visiting, a few days ago, the Montreal school, and cannot too highly recommend its system of instruction to those who wish to acquire some knowledge of modelling, freehand drawing and building construction, and am glad to be in a position to give herein a short description of the school. The school occupies three buildings, completely independent from one another. Two are antique but massive and well built buildings facing the Champs de Mars on St. Gabriel street, and forming the two angles of Fortification Lane, which begins at this point. The school is maintained at the expense of the Provincial Government, and is open free of charge to all male pupils above the age of fifteen years. It opens on the 5th of November in each year, to close on 5th April. Applications for admission are received by the Professors at the class rooms and are presented by the candidates in person, accompanied by a letter of recommendation from their employers. As the number of applications for admission in some of the classes are sometimes in excess of the number that can be immediately admitted, it becomes necessary for the later applicants to wait until vacancies occur; they are then admitted in the order of their applications. The only exception to this rule is made when the number waiting is more than enough to fill the probable vacancies for the season—then preference is given to those whose occupations require a knowledge of the study sought.

Pupils who may obtain admission to a class for which they are not properly qualified, are referred by their Professor to such class as may be deemed proper. They are then entered as applicants for this class, if they so desire, but are subject to the same conditions as new applicants of the same date. Each pupil on being admitted to a certain class is required to make a deposit of one dollar, which is returned if he has not been absent more than four times during the session. But in any case, when a pupil has sufficient reason for absenting himself, he should always report to his Professor in order to retain his position in the school. At the close of the session pupils must take charge of their drawing boards, instruments, etc., and all drawings or other works executed in the school are retained during the session; at the close the Council may retain such works as it considers desirable, the remainder being returned to the pupils.

The building situated on the left hand side of Fortification Lane is three stories high and contains in the basement, which is reached by a side entrance, the class in lithography, with an attendance of 18 pupils, having at their head Mr. J. A. P. Labelle as professor. The instruction commences with the preparation of the lithographic stone for work, and proceeds by regular steps till the pupil is able to finish a drawing on the stone, ready for the press. Instruction is given in engraving on stone, crayon and pen and ink work. The stone and other materials required in the class room are provided free of cost to the pupil. This class meets every Monday and Friday between 7.30 and 9.30 p.m.

The ground floor is occupied by the administrative offices of the school, and the first floor by some government offices. The second floor is occupied by the architectural class and also by the pattern making class. The class of architectural drawing possess a fine room measuring about 15 x 50 feet, well equipped with drawing tables and other requisites, and has actually 23 pupils, following their courses under the guidance of Messrs. Henry J. Peters and P. N. Peard, both architects actually engaged in the practice of their profession. In this class, although mostly intended for carpenters, builders, cabinet makers, etc., the instruction is, however, adapted as far as possible to the requirements of the pupils. Exercises are given in geometry and projection, and pupils are instructed in the details of framing, plans and elevations of buildings, and the preparation of working drawings. Several architectural students I have noticed are following this course. This class meets on Mondays and Fridays from 7.30 to 9.30 p.m.

Next to this class is the pattern making class for boot and shoe makers, which probably does not interest us very much. This class also meets every Monday and Friday, with Mr. Jos. Godin as professor. It is established for the purpose of giving practical instruction for the study and practice of artistic pattern cutting for boots and shoes of all kinds.

In the building situated at the right hand side of Fortification Lane, which is about of the same style as the one first mentioned, is on the ground floor the modelling and wood carving class, two very important factors in architectural decoration. The room occupied by this class, although small in size and of very plain appearance, has an artistic look about it with it's plaster models of Renaissance compositions hung on the wall, and statues and busts of historical personages reposing on pedestals. This class is intended to give instruction to all who use the chisel, but more particularly to marble and stone cutters, wood carvers, etc. The pipe clay which is used in modelling can be softened as often as required, thus enabling the pupil to work with ease and rapidity, obtain quick results, and become familar with form; he first gives to the mass of clay the rough outline of the object he desires to reproduce, and then finishes it by the aid of the tools. The clay required is provided free of charge. Pupils who join this class have to be well up in freehand drawing, but in the case of stone cutters this condition is not rigidly exacted. I believe that this is the class that could do the most towards developing the artistic taste of the students, especially the students of architecture, affording as it does the opportunity to study with advantage the human figure, which is so essential a part of the education of every artist. This class, notwithstanding its importance, possesses only 18 students, five of whom are devoting themselves to wood carving. It is open every Tuesday and Friday from 7.30 to 9.30 p.m. under the supervision of Mr. J. O. Gratton, sculptor.

Now pass on to the Stair Building and Building Construction Class, a department of interest to builders and architectural students who wish to gain knowledge of a practical character. The class is composed of 26 pupils, headed by Prof. L. H. Bloum, who teaches them all matters connected with construction of buildings, and who gets them to make plans for stairs and other work, and execute the same in the class rooms adjoining the Modelling Class. Special attention is given to the important branch of stair building. Tools and materials are provided by the school free of charge.

On the first floor of this building, over the Modelling and Stair Building Classes, is the Freehand Drawing Class—one of the most important at the school—both as regards the work it accomplishes and the number of students who attend it's courses. This department is under the charge of Professor E. Dyonnet, A.R.C.A., and is divided into two classes—the elementary and the advanced class. The elementary class is for those who have but a vague idea of drawing, and is intended as preparatory to the advanced class. The pupils begin by drawing differently shaped geometrical blocks, commencing with the most simple, and progressing to more complicated shapes. This method of drawing from solids from the very first has been generally adopted in all the best drawing schools of Europe. It shows the pupil in a more intelligible way than any other method, the first difficulties of outline, perspective, light and shade and tone, and as the pupil's intelligence is appealed to, there is comparatively little difficulty in showing him how these difficulties are to be overcome. After one season spent in the elementary class, the pupil who has made sufficient progress is promoted to the advanced class. He soon finds out that the principles he has learned in the first year are continually applied in the second. His eye and hand now gain sufficient accuracy and precision to enable him to draw parts of the figure from plaster casts. The simplest pieces are given at first, but as difficulties are overcome, more complicated ones are tried, until the full length antique figure is reached, after which he will soon be prepared to draw directly from the living model. This department is composed of about 30 pupils, who meet on Monday and Thursday for the Elementary Class, and Tuesday and Friday for the Advanced Class.

On Tuesday and Thursday pupils composing the Mechanical Drawing Class have their courses in the rooms occupied on Mondays and Fridays by the Architectural Drawing Class. The class is conducted by Messrs. J. T. Gardham and J. Clement. It is chiefly intended for those who follow mechanical pursuits, and to apprentices and others connected with machine building it proves to be of great value. It is aimed to make the instruction of a thoroughly practical character. Blue prints and figured sketches of familiar details of machine design are supplied, from which the pupils are required to make general drawings, etc., and to follow as far as possible the usual office practice.

This completes the number of classes contained in the two buildings forming the angles of St. Gabriel Street and Fortification Lane. On the other side of St. Gabriel Street, opposite the school, and adjoining the Champs de Mars, is old St. Gabriel Church, an historical relic of the last century. It was built in 1792, and is the first Protestant church built in Montreal. It is now the property of the Provincial Government, and is occupied to-day by the Plumbing Class of this school. It has been used during the past few years by the Decorative Painting Class, which was abandoned this year. There are two professors—Messrs. W. Britton and J. A. Peard. The class is under the immediate charge of a Committee of the Master Plumbers' Association recently formed, and which I hear will apply at the next session of the Legislature for an act of incorporation. The class has an actual attendance of about 45 pupils, and meets every Monday, and Friday from 7.30 to 9.30 p.m. The class has been arranged for apprentices, journeymen and foremen engaged in any branch of plumbing. The class room is equipped for about fifty pupils, each member having a gas furnace for melting solder and a drawer for holding tools. Instruction is given on such subjects as lead bossing, pipe bending, soldering and wiping joints, lead burning, water closets and their fittings, water waste preventors, baths, lavatories and sinks, taps, soil pipes, connection of drain to sewer, ventilation of soil pipes and drains, sizes of pipes, etc.; water supply, house cisterns, their construction, position and management; the use of tools, etc., etc. All materials are supplied free of charge.

It is in old St. Gabriel church that every year is held an exhibition of the most creditable examples of the work accomplished by the pupils of the different classes of the school during the session. As the pupils are at present just commencing the session, it is difficult to judge of their merit by their work, as they have hardly had time to do any yet, but I propose at the next annual exhibition of the school, which in all probability will be held as usual in April, to give a description of the principal works executed by the pupils during the present session.

BUILDING ACCIDENT.

The roof of a six storey building in course of erection at the corner of Craig Street and Place d'Armes Hill, for the Montreal Street Railway Company, fell in a few days ago. All but three of the twenty-one workmen employed on the roof at the time received sufficient warning of the approaching accident to enable them to safely reach the walls before the crash came. The others were carried down with the roof. Two of them are reported to have died from their injuries. Messrs. J. W. & E. C. Hopkins are the architects of the building. Ald. Dubuc is the contractor for the stone work, Ald. Brunet for the brickwork, Ald. Robert for the woodwork, and the Dominion Bridge Co. for the structural iron. All sorts of causes are being assigned for the accident, but I prefer not to mention any of them prior to the investigation, which I understand will shortly be held.

RECENT CANADIAN PATENTS.

Patent No. 47,669, has been granted to Jules Colas, Montreal, for a draining well.

Louis Rosenfield, New York, has been given a patent No. 47,064, for a hoisting apparatus.

A patent No. 47,044, for a door knob, has been granted to Albert E. White, Dutton, Ont.

Messrs. Darling Bros., Montreal, have been granted a patent, No. 46,961, for a combined bracket and shelf.

A patent No. 47,070 for an elevator brake, has been secured by Ernst C. Heydenreich, Mount Clemens, Mich.

John Heard, Strathroy, Ont., has been given a patent on moulds for forming concrete into pipes for drains, &c.

Patent No. 46,669 has been granted to Geo. Belanger and others of Quebec, for a cement formed of quartz and other substances.

Samuel John Laughlin and James Hough, of Guelph, Ont., have received a patent No. 47,003, for a sketching and designing table.

A patent on apparatus for repairing asphalt pavements, was granted on Sept., 20th, to the Western Paving and Supply Co., Chicago.

Jas. Peckover, Harrisburg, and John E. Johnson, Philadelphia, Pa., have obtained a patent dated 24th Sept., 1894, on a stone sawing machine.

Theophile E. Ayotte and Arthur A. Charbonneau, Montreal, were given a patent, Sept. 26th, on a process for making brick and artificial stone.

Hugh C. Baird and Oliver Baird, of Parkhill, Ont., assignees of James and Eli Elliott, of Wingham, Ont., have obtained a patent No. 47,054, on a brick and tile machine.

Charles H. Dalrymple, Detroit, Mich., and Chas. E. Hassey, Hamilton, Ont., have been granted a patent, No. 47,031, on a roofing composition, consisting of sheets of wood fibre, rendered impervious to moisture, and having abutting up-turned edges, the battens provided with a groove in their outer edge which receives the up-turned edges of these, sheets to close the joints.

PUBLICATIONS.

The Review of Reviews for November, has some pertinent notes on European politics and editorial tributes to the memory of Dr. Oliver Wendell Holmes and Professor David Swing, of Chicago.

"The Art Schools of America," "The Great British Northwest Territory," "The Chiefs of the American Press," and the "Public Library Movement," are amongst the Cosmopolitan's table of contents for November.

A correspondent of the Illustrated Carpenter and Builder expresses the opinion that the best form of roof for a cottage, if expense is not a consideration, is to cover the rafters with 7/8in. dry boarding, and over this nail a layer of inodorous felt; then comes a row of vertical battens fixed to top of rafters, then the ordinary slate battens. The old slates may be reused, if sound and fit for reuse, and, in fact, may be preferable to new ones in some cases.

CORRESPONDENCE.

Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not resume responsibility for the opinions of correspondents.]

ARCHITECTURAL COMPETITIONS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Apropos of your remarks on Competitions last month, the question has often been asked "Whether better results attend the giving of a commission to one architect or a Competition in which a large number of the profession are invited to send in designs." The answer is altogether conditional. Competition properly conducted for public buildings will probably call forth the more thoughtful and skilful design. Much depends, however, on the terms of invitation and the discretion of the committee of selection and their assessors.

The competitive system is becoming discredited amongst architects of known experience and ability in Canada, because of the unbusinesslike way in which competitions are conducted and the flagrant injustice of the awards—a condition which obtained in England at no very distant date, until the architects combined in their endeavor to obtain fairness and justice. There were many years of isolated outbursts of indignant remonstrance from disappointed competitors against committees and boards for unfair decisions before the obvious remedy was seen, or at any rate applied. The conduct of Competitions will be what those who enter into them are collectively content to allow them to be, and it is evident that only by combining together in one solid phalanx against the loose system at present in vogue, can the standard be raised. If promotors of Competitions were made to see that professional men of ability would not respond unless an assessor of unquestioned standing were appointed, whose advice on the merits of the design would be accepted, and certain broad rules for the conduct of Competitions be adopted, a healthier system would soon be established.

I am aware that the Ontario Association of Architects have formulated some excellent rules which, with little amendment, would serve the purpose suggested, but they remain practically a dead letter, because their authors do not insist on their adoption, and it is left to anybody or nobody to take the initiative of enforcing them. The conditions for the conduct of a Competition should be framed with the single purpose of obtaining a perfectly fair competition, and having been issued, should be rigidly enforced. They should very definitely state the amount to be expended, and that all designs which cannot be carried out for that amount will be disqualified, that the chosen design will not be accepted unless bona-fide tenders can be obtained within 5 in excess of the figure stated. There should be no irksome restrictions in the conditions or arbitrary dictation of plan. I remember hearing Mr. Waterhouse, R. A., at the R. I. B. A., say: "I would have every competitor put as nearly as possible in the position of an architect acting for a private client, who, though he may have suggested his requirements, would probably listen to his professional adviser, if he gave good reasons for not literally adhering to them in all cases." If Competition designing is to be made successful, it must be spontaneous and free. Instructions which are ambiguous and which a competitor feels he cannot alter or modify without being disqualified, are prejudicial to the end in view of Competition, that of obtaining the most skilful design at a given cost. In conclusion let me say, that as far as Toronto is concerned, nothing can be accomplished until the architects act more in concert with each other. To this end they should meet together oftener and probably carry out the scheme of a common meeting and reading room as outlined by "A City Member" in the October issue of the CANADIAN ARCHITECT AND BUILDER.

Yours truly,

J. WILSON SIDDALL.

ONTARIO ASSOCIATION OF ARCHITECTS.

At the supplemental examinations held in October the following students came up and passed:—

S. F. Smith, 2nd Intermediate; C. P. Band and G. E. Stephenson, 1st Intermediate.

E. Langley, who intended to come up for the 1st Intermediate in March, but was prevented by illness, was allowed to take at the supplemental examination a full examination on the 1st Intermediate subjects, and passed.

Mr. C. H. C. Wright, Lecturer in Architecture at the School of Practical Science, will give a lecture on Graphic Statics to the Association on the evening of November 16th. The lecture will be given at the Canadian Institute, 58 Richmond street east, and will begin at 8 o'clock. This lecture, being on a technical subject, has not been announced as a public lecture, but we are authorized to state that any person interested in the subject will be welcome.

Judging by the new lines of furniture displayed by the leading dealers and manufacturers, a reaction is setting in towards natural finish in oak. Very little antique oak is shown, and the peculiar and fanciful colorings so popular a year ago, are nowhere to be seen. If the wood is toned at all, the tendency is toward shades of yellow or to a slightly reddish cast.

ILLUSTRATIONS.

THE TOWER OF PALAZZO VECCHIO, FLORENCE, ITALY.—DRAWN BY MR. E. J. BIRD.

This tower, so admirable for its solid construction, united to graceful proportions, is ninety-four metres high.

The Palazzo itself was raised by the genius of the architect, Arnolfo di Cambio, in 1298, A.D., and has been enlarged at different times by Michelozzi (1434) and Varsari (1550). This palace was the seat of the Signoria of Florence, then the principal offices of the Granducal Government, and at present belongs to the municipality, the offices of which are here.

WROUGHT IRON FENCE AND GATES TO RESIDENCE OF MR. A. A. ALLAN, TORONTO—GORDON & HELLIWELL, ARCHITECTS EXECUTED BY SHIPWAY MFG. CO., TORONTO.

HOUSE FOR MR. DUBUC, MONTREAL.—A. RAZA, ARCHITECT, MONTREAL.

DESIGN FOR INSURANCE BUILDING, GALT, ONT.,—J. A. ELLIS, ARCHITECT, TORONTO JUNCTION.

OLD MEN'S REFUGE, VANCOUVER, B. C.—R. MACKAY FRIPP, F.R.I.B.A., ARCHITECT, VANCOUVER.

IMPACT TESTS OF CAST-IRON PIPES UNDER HYDROSTATIC PRESSURE.

REFERRING to a frequent specification requirement for striking a cast-iron pipe with a hammer while it is subjected to heavy water pressure, S. Groves writes in a recent number of The Foundry that he conducted some experiments to determine the effect of those tests when in 1889 he was engaged with a large English pipe foundry.

"Two socket and spigot pipes 4 inches in diameter by 9 feet long by three-eighths inch thick—one cast vertically, the other cast at an angle—were subjected in the hydraulic proving press to a hydrostatic pressure of 260 pounds per square inch, and while under this condition a wrought-iron ball weighing 1½ lbs. was let fall upon a chalk line mark on the body of the pipe, at given points and from varying heights, as indicated by Figs. 1 and 2. The pipes are then taken out of the press and broken logitudinally into two parts. On the inside of each pipe, at the points where the ball had struck dead upon the center line, was a star-shaped fracture, Fig. 4. The fractured half of each pipe was then broken into two parts, and each piece upon which a blow had been struck was carefully broken through the star-shaped fracture. In each section was an oxydized fracture penetrating through the inside skin of the pipe into the body metal,

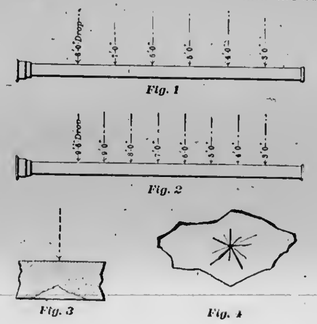

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Fig. 3, and in no case was the depth less than three thirty-seconds inch, the greatest being five thirty-seconds inch.

"The following is a table showing the depth of the respective fractures:

PIPE CAST VERTICALLY.

Drop.	Depth of Fracture.
3 feet.	Slight.
4 "	3-32 inch.
5 "	Slight.
6 "	Slight.
7 "	⅛ inch.
8 "	5-32 inch.

PIPE CAST AT AN ANGLE.

Drop.	Depth of Fracture.
3 feet.	Slight.
4 "	Slight.
5 "	⅛ inch.
6 "	Slight.
8 "	5-32 inch.
8 "	3-32 inch.
9 "	Slight.
9 " 6 inches.	3-32 inch.

"The cases marked 'slight,' were due to the deflection of the ball, in consequence of not falling dead upon the centre line. In every instance where the ball struck true a serious fracture resulted.

"Instead, therefore, of the hammer-sounding test being a safeguard, it is actually a danger; worse than a variation in body thickness of one-sixteenth of an inch, for which many a pipe has been sent to the scrap heap.

STUDENTS' DEPARTMENT.

DISCOVERIES IN ARCHITECTURE.*

DISCOVERIES of things absolutely and always unknown are always rare; and in some branches of study—architecture among others—are in the nature of things impossible. But in the sense of finding out or uncovering something previously unknown to the discoverer discovery occurs frequently, and it is by far the most healthy, the most interesting, and the most successful form of study. I propose then, in this lecture, to begin with the simple, but most valuable, discoveries which you as students must make for yourselves if you are really to master the art of Architecture; and then to proceed to notice some of the discoveries which have taken place in recent years which are more brilliant in their character and relate to architectural matters that have long lain hid. I propose to distinguish these, and call them respectively personal and public discoveries; for there is this distinction certainly between them, that the discoveries which a student makes are mostly of importance to him personally, but are not such as need be made public. Those which an explorer may make are perhaps quite as important to the general public as to the discoverer, and are usually published to the world.

The information you obtain in the offices where you work, or from attending classes like those about to begin in this college, is hardly discovery; it is instruction, and the worst of it is that, as it is not difficult to get, it is very apt not to stick in the memory. The information discovered by making researches on your own account is mostly obtained with difficulty and trouble, but it is seldom, if ever, forgotten. You may make discoveries in a library. For example, let us say that you are advised to read a handbook, say "Fergusson's History," and you do so, finding it perhaps a rather laborious task, as the reading of any condensed book always must be. You notice, however, that the numerous wood cuts all have reference to the names of writers from whose publications they are copied, and having access to books, say to the Institute library, or that at South Kensington, or some other collection of books, you begin to consult some of the original authorities, and among them you discover some book of which the illustrations or the letter-press, or both, bear on what you have been reading about, and are full and clear and interesting. The book you have discovered only occupies a corner of the vast field that Fergusson travels over; but then the writer really has the leisure to take possession of that corner, and to throw a clear light upon it. The mere fact that you have to some extent unearthed the book for yourself helps to give a zest to the reading of it, or the examination of its illustrations. It is a discovery. Nor is it in a public library only that such discoveries can be made. In any collection of books or photographs or prints to which you have access, and on the shelves of second-hand booksellers and the tables of bookstalls, you can have the same good fortune. I, for example, myself possess not a few valuable books on subjects connected with architecture which first came to my knowledge through finding them on book stalls. This reference to discovering books ought not to be made without alluding to the help to be got from one very valuable book of reference, which just now possesses a melancholy interest for some of us. I allude to the "Dictionary of Architecture," of the Architectural Publication Society, a work bristling with sign-posts—if I may use such a phrase—calculated to direct the student (in his search for knowledge) to the best sources of information. In almost all the articles the most copious lists of references occur, and it is of the greatest use to a real student to have sources of information so liberally spread before his view. This work (begun by a circle of architects, some of whom only have survived to see its completion) would have been left unfinished but for the indomitable energy and public spirit of Mr. Cates, and the learning and patience of the late Mr. Wyatt Papworth, and it is impossible just now to mention the "Dictionary" without alluding briefly to the great loss which architecture has within the last few weeks sustained in the recent death of the last-named architect (Mr. Papworth). He was full of accurate and well-digested information on every subject connected with our profession. He was an indefatigable, systematic and accurate worker, singularly quiet and simple in his manner and bearing, and was universally esteemed. In many ways his vast store of technical information has been made useful to the members of his profession. To you, gentlemen, his work, as editing Gwilt's "Dictionary," the value of which he practically doubled by the additions he made to it, is pretty sure to be familiar; but there are many others, and many important memorials of him in the literature of our profession, and his death leaves a blank which it will not be easy to fill up. To return, however, to students' discoveries—of which, by the bye, the late Mr. Papworth made many and valuable ones—architecture can be better learned from buildings than from books, and it is in visits to buildings, ancient and modern, that you will make the discoveries that will be of most use to you. The most simple building, if it is good, has some secrets, if you can but make them out. Why is it pleasing? Why are there certain irregularities? How is it constructed? What has been its history as a structure? These, and such-like questions, should present themselves to the mind, and if we can but discover the answer to one such question, the visit to the building in respect of which it is asked will have been fruitful. Among the most interesting features of ancient buildings are the traces of their history which they bear indicating the successive enlargements, alterations, rebuildings and so forth, which they have undergone, and the discoveries of this sort which a keen student, examining an old manor house or a church, a cathedral or a castle, may make for himself, are extremely interesting and extremely instructive. One of the most complete accounts of such a series of discoveries, illustrating the past history of a great building by its actual visible marks, exists in the account of Canterbury Cathedral, from the pen of the late Prof. Willis. No man during the present time of careful research has been more keen or more successful in his examination of ancient buildings than he, and this record is a good example of the manner in which it is possible to make them tell the story of their varied changes, alterations, rebuildings and extensions. Even without a tenth part of the minuteness and elaboration of Willis's investigation, if you simply establish the broad divisions of Saxon, Norman, Early English and so forth, in a building with a chequered history, and recognize the most obvious features of each period, you will have discovered the leading facts in the history of the building. In this sort of research it is peculiarly true that "to him that hath shall be given." To a person even of artistic taste and power of observation, entirely devoid of architectural knowledge, a building is almost a sealed book; but when you have got even a little knowledge from other sources a building begins to be legible. As an example, I would suggest to any student who has read something of the changes in tracery, in vaulting, and in mouldings which occur in English architecture, that when he has obtained some knowledge of these things from books he should go to Westminster Abbey cloister, getting first from Scott's book the dates at which it was done, and identify the different features of each period, and the changes both in feature and general proportions. He will find that he has discovered a good deal of what is really meant by the terms Early English, Decorated and Perpendicular. It is possible to make discoveries on drawings of buildings as well as on the buildings themselves. An example of what I mean: If you take the drawings of one of Sir Christopher Wren's churches, and examine them carefully, you may perhaps discover some of the principles upon which he designed them. He was a very orderly and mathematical worker. He had strongly impressed upon his mind the conviction that the establishment of geometrical relations between the main dimensions of his building was a means of securing that their proportions should be pleasing, and if, with this clue in your mind, and a pair of dividers in your hand, you examine a series of engravings giving the plans, sections, and elevations of his churches, and St. Paul's Cathedral, you will, I think, find it possible, and extremely instructive, to discover some of his methods of working. The plan and sections of St. Stephen's Church, Walbrook, generally recognized as the best among Wren's many successful interiors, will be very good to begin with. A famous place to investigate is a good museum. I doubt whether any one of you has seen, let alone studied in, all the museums of London which furnish information about architecture, though I hope most of you have studied, or will study in some.

That an architect should overhaul the church in any village of town where he may be, if it be of good design or possessed of features of interest, is, I hope, so much a matter of course, that I do not stop to point out how much can be discovered and appropriated in journeys and country rambles; but I am disposed to dwell upon the modern work which awaits the traveller in various parts of England. The country is now thickly sprinkled with fine mansions and smaller country houses, nearly all of them good, and many of them extraordinarily good.

*Abstracts from an inaugural lecture delivered at University College, London, on Thursday evening, October 11, 1894, by Prof T. Roger Smith, F.R.I.B.A.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' COMPETITION.

THE publisher of the CANADIAN ARCHITECT AND BUILDER invites designs from students for a Muskoka Summer Cottage to cost not more than $1,000. The accommodation required is a generous living room, with pantry and kitchen; five bed rooms, and provision for fuel.

The cottage is to be erected on a wooded island or point, the principal view being southward. The actual site is rocky and broken, with no extent of level surface, the space to be occupied by the cottage varying in level some 8 or 10 feet.

Competitors are required to submit floor plans and two elevations, unless accompanied by a perspective, in which case one elevation will be sufficient.

Each design (including elevations, plans, etc.,) must be made on a single sheet of heavy white drawing paper or bristol board, 14×20 inches in size, and must be drawn sufficiently coarse to have the proper appearance when reduced by the photo-engraver to one half the above size. The drawing must be made in FIRM, STRONG LINES, with PEN and BLACK ink. No color or brush work will be allowed. Each drawing must be marked only with the *nom de plume* of its author. The author's full name and address, enclosed in sealed envelope, with *nom de plume* on the outside, must accompany each drawing submitted. This envelope will not be opened till after the competition shall have been decided. There is also required a brief description of the design, mentioning the materials proposed to be employed in the construction of the building.

Drawings for this competition must reach the office of the CANADIAN ARCHITECT AND BUILDER, Confederation Life Building, Toronto, not later than the 20th of December, 1894.

The first premium is the sum of $10; the second, $5; the third, one year's subscription to the CANADIAN ARCHITECT AND BUILDER. The decision as to the merits of the designs submitted will be made by three members of the Ontario Association of Architects. This decision will be final. The publisher of the ARCHITECT AND BUILDER reserves the right to publish such of the designs submitted as may be deemed suitable, and to withhold the award should none of the designs be found to satisfactorily meet the requirements.

All drawings will be returned to their authors within a reasonable time after the competition is decided.

Architects are debarred from this competition.

WHEN the national pike bridge, west of Richmond, Ind., was in process of construction, says the Indianapolis Sentinel, the workmen at the west side of White Water river dug down to find a solid foundation. They struck a great and seemingly bottomless bed of quicksand. Vainly they labored to find a safe resting-place for the foundation. Finally the civil engineer and the contractor struck on a novel expedient to overcome the difficulty. They sent men all through the country to buy wool. This wool they packed into the quicksand till the sand would take no more. At last, on this wooly foundation, the rocks were laid and to-day the western abutment of the old national bridge rests on a bed of compressed wool.

DECORATION AND FURNITURE

THE EXTERNAL COLOUR-DECORATION OF BUILDINGS.*

By T. G. Cesare Formilli.

Amongst the many considerations suggested by the works of the old masters in Art, there is one concerning the external decoration of houses which leads to the enquiries: Why is it that to-day, when the words "old masters" are on the lips of all, when we consult and study them, that we do not take examples from the various methods that they had of externally decorating their edifices with such beautiful effect? and why do we not also unite coloring with architecture? Colour does not disturb form in any way; in fact, when colour is well-conceived, it greatly helps to bring out the full beauty of form. The Assyrian Art, the Egyptian, Greek, Roman, Arabian, Gothic, and finally, the Art of the fifteenth century, entered into the decoration of innumerable edifices of great importance, some with monochrome colours and some in polychrome; whilst we, with few exceptions, when we want to do something above the ordinary level, generally resort simply to the usual terra-cotta or stone of uniform colour and to very little else.

We must, however, here note that, in spite of the general similarity of the external decoration of the present age, we see in them from time to time a tendency to more closely study the old masters, and we notice a certain revival of old ideas of great artistic value relating to external decorations in colour.

There is much that could be said about the art of uniting colour with architecture in the Greek and Roman periods, but the time is too limited on this occasion to attempt to cover so extensive a field. I will, therefore, limit myself to a few remarks about the methods adopted by the fifteenth-century artists for adding beauty and variety to their edifices. I ought also to say that amongst the many and varied styles of external decoration of the different artistic periods in different countries, that used by the fifteenth-century masters, which lends itself so particularly to our requirements, greatly surpassed every other style of decoration which had, up to that period, been used. What have we, it may be asked, more beautiful in external decoration than the immortal majolica of the Della Robbia, and the graffitos, chiaroscuros and frescoes of Polidoro da Caravaggio, Pellegrino da Bologna, Maturino, Fiorentino, Guillo Romano, and Raffaelle? These artists, who possessed such refined taste, covered many and many external walls of houses and palaces, which, for the proportion of the windows, the elegance of the columns, and that of the cornices, have excited immense admiration, and yet those beautiful and various decorations, framed, as it may be said, by the surrounding elements of architecture, have hardly been considered worthy of study, except in very rare cases.

Rome, Florence, Venice, and many other principal and secondary cities of Italy can give immmerable examples of the beautiful art of external decoration, which, in virtue of the material used and the mode in which the work was done, have endured through many centuries, as well as the architectural stonework which encloses them.

However, we must note that in these golden times the term "decorator" conveyed something more elevated and noble than it is frequently understood to mean to-day. In fact, in the past, a Michelangelo, a Raffaelle, a Cellini, were embraced in the title of decorator. Whereas in these days it is rarely that we see a work of industrial art executed by an artist of high reputation; there seems to be a prejudice against such work. Why then, do we not entirely abolish this prejudice? Why do not artists who have great names, and those who have not, return to those good and wise traditions of the old times? What variety, what elegance of effect might be added to the many houses that are now being constructed with so much good architectural taste if there were introduced in some or all of the blank spaces decorations of majolica, graffito, chiaroscuro or fresco as in the fifteenth century.

Let us, however, now pass on to the principal methods of external decoration most used in that period, beginning with that of majolica.

Besides being extremely beautiful, the majolica decoration has the advantage of preserving the walls by preventing the penetration of moisture into the interior, and thereby protecting in the same way both the owner's property and the occupier's health. As is generally known, external decoration in majolica is often seen in the Southern climates, whereas, in England, if it is used at all, it is chiefly for interiors. If we ought to believe in the old Latin saying, utile dulce, majolica would hardly be selected for the internal decoration of dwelling-houses in cold climates, for although in a certain sense it must be considered useful, it certainly would tend to discomfort indoors under ordinary circumstances during cold weather.

Externally, however, as already said, it protects the walls from rain, fog, and from dirt; presenting at the same time to the eye a magnificent and varied effect. We may imagine the effect of the front of a house well designed by the architect for the application of majolica, having beautiful friezes, medallions, panels, &c., in this material, and of the truly artistic creation in the sober sense in which the old masters intended. A big frieze, as made by Luca, Giovanni, or Andrea Della Robbia, with spaces between the windows, fitted with beautiful symbolical figures, representing, for example, scenes from family life, or fitted with scenes of child life, as Andrea fitted the famous medallions which decorate the space above the arches of the Hospital of the Innocents, in Florence.

What beautiful and sublime external decoration is made by the five figures of Giovanni Della Robbia, in Pistoria, namely, Faith, Hope, Charity, Prudence and Justice; also by the immortal frieze, called "The Seven Works of Mercy," of which beautiful copies can be seen at South Kensington Museum, and which are good in any case as an inspiration in that class of external decoration. Not less important or beautiful are the medallions of the arms of the King of Anjou, and the months of the year, both by Luca, and also found among the many treasures of the same Museum.

It would be too long to enumerate the many examples of decoration in majolica by the Della Robbia's family, who began with Michael, born about 1320, followed by Luca about 1399, by Andrea in 1435, and by Girolamo in 1488. Afterwards one branch of this family became almost French, and finished with Guido Della Robbia, who did not reach the age of touching the clay, but died in 1625 at the age of only five years.

Another system of external decoration not less beautiful and well adapted to resist atmospheric changes is without doubt that of graffito, which was adopted with immense technical and artistic knowledge in the renaissance of the Italian Art.

Such decoration, whether it be for its weathering powers in severe climates or for the magnificent artistic and at the same time subdued effect which it produces to the eye, certainly merits being considered as beautiful as decoration in majolica.

On the Continent, and especially in Germany and Italy, the art of Graffito is extensively used, but here in England many must regret that graffito decoration has been almost entirely neglected. It is difficult to account for this unless it is due to the erroneous impressions that the English climate would injuriously affect the work, or that it may be too expensive for general application.

Regarding the cost, I need only say that it would compare favorably with any decoration, even if it were of the simplest description, in stone or terra-cotta.

As to the durability of graffito, it is, if properly executed, quite capable of resisting heat, frost and rain, because it presents a very hard surface, and is much less porous than ordinary stones or bricks, whilst it lends itself to being easily washed, which is an advantage in foggy and smoky atmospheres. Of the very few examples of graffito existing in London, that which is at South Kensington, although not executed according to the method of real graffito, affords nevertheless good evidence that decorations of this character do not suffer materially from long exposure to atmospheric changes. If they are a little darker in tone than when they were executed, they still are perfectly distinct, and, without doubt, of a finer tone and more harmonious than when done by the artist. Here I ought to add that the work just mentioned is cut much deeper than graffito as intended by the old masters in this art—masters to whom we feel deeply grateful for having added this treasure to their already invaluable bequests.

Vasari wrote of the graffito of his day, and gave considerable information about it. He referred to it in words which may be translated as follows: "Artists have another sort of art, which is called graffito, and serves for ornamenting the fronts of houses and palaces, which may be quickly decorated by such a system, and more surely resists the rain. Its durability is entirely due to the etching on the wall instead of being simply drawn in chiaroscuro or in colours." He then describes the process of preparing and tinting the cement or plaster which is to be laid on the part of the building to be decorated, and which forms the background of the work, and explains how this is afterwards covered with a wash of lime of travertino, through which the lines are etched with an iron point. He further describes how backgrounds are obtained by the entire removal of the surface wash, and shows how strong projecting shadows for grotesque figures or designs of foliage may be produced by adding stronger shades of the same color to the background.

Referring again to the graffitos at South Kensington, they may be described as low relief in graffito rather than graffito proper, because the cut into the plaster or cement bed is excessively deep. The depth of the cut made with the iron or steel point by the artist in that particular work is a disadvantage, necessitated by plastering on the final coat instead of merely washing it on. So deep a cut gives a hard appearance to the design, and impedes the water from running off the walls, whilst tending to accumulate dirt. The true Italian graffito is without this inconvenient feature, because the depth of the cut is scarcely perceptible. The cut or score made by the instrument does not generally exceed the thickness of a sheet of drawing paper, or in other words, very little more than the thickness of the surface layer with which the bed-work is covered. Extremely beautiful effects can be produced under these conditions, perhaps more beautiful than can be obtained with a soft-pencil on a rough paper. The weight of the leaning point of iron is itself sufficient to remove the light surface, and to make the dark background appear without fatigue to the hand.

In some backgrounds colors in monochrome are sometimes added, and these are treated just as you treat fresco, which is very easy after experience has taught the difference between the tint in its wet and dry state. Some of the finest and richest effects are reached by the addition of gilding to some part of the graffito, as ribbons, fruits, arms, &c. The gold, however, must be added when the graffito is perfectly dry.

Naturally there is much in graffito decoration that experience teaches, but it is not very difficult to execute, and it seems to be deserving of more attention in these days of progress, in virtue of its durability as well as of the excellent effects it lends itself to producing. There seems to be a good field open for teaching graffito decoration in the art schools, which have been so largely established in this country.

There are still other modes of decorating the exterior of edifices which were adopted by the fifteenth-century artist—namely, that of chiaroscuro in fresco, and fresco in colors. The first has, at a distance, all the appearance of graffito, and, although the design is not cut, it has similar color and effect.

Much was done in this style by Maturino Fiorentino and Polidoro da Caravaggio, both of whom arrived to the highest point in this art of decoration with their immortal work of chiaroscuro in Fresco in Via della Maschera d' Oro in Rome. Many other examples could also be mentioned, but as this work is the most important among the others, it will suffice as an illustration of this beautiful art. The frieze representing historical scenes is the most important decoration, and in a certain sense it recalls to mind the sequence of pictures which compose the triumph of Cesare, by Mantegna, at Hampton Court. Speaking of fresco, what is meant is the real Italian fresco, and not tempera or incausto, which is occasionally confused with it. As an external decoration it may be considered to be truly ideal, and it is to be regretted that in England it appears to be absolutely out of fashion.

Outside fresco, when it is done with good and pure earth colors, upon suitable lime mixed with much sand and puzzolana of that sort which the Romans used on the Colosseum, becomes very solid, hard, lasting and washable, just like compact and durable stone.

It is really to be regretted that to-day the exterior of buildings is so much limited in the matter of decoration to frames, columns, or, in a few words, to architectural mouldings, whereas the old masters of nearly all ages introduced into their edifices all that contributed beauty. Why, it may be asked, render so poor the mother of all Arts—the one which more directly speaks to our souls, which is so impressive, which cheers and covers us?

* A paper read at a meeting of the "Art-workers' Guild," London, on October 5.

A STATEMENT IN FAVOR OF HOLLOW BRICK WALLS.

By E. Boyden, Architect, Worcester, Mass.

In order to give a thorough knowledge of what is required, I quote the report made by the government officer of the Ordnance Department U. S. A., at Watertown Arsenal, of a test made of seven bricks from Providence, R.I., for the Norcross Brothers, of Worcester, Mass., Sept. 14, 1892.

Test Numbers.		Dimensions in Inches.			Sectional Area	First Crack. Lbs.	Ultimate Str. Total lbs.	Ultimate Str. Lbs. Per Sq. Inch.
8698	No. 1. Long Island Brick Co.	2.45	3.80	8.18	28.32	58,000	128,100	4,492
8699	No. 2. Danvers	2.00	3.72	7.94	29.54	91,800	194,700	6,591
8700	No. 3. N. E. Steam B. Co. Rough Pav.	2.21	3.80	7.78	29.56	132,000	372,300	12,612
8702	No. 4. N. E. Steam B. Co. Smooth Pav.	2.20	3.51	7.78	27.31	177,000	383,900	14,057
8703	No. 5. N. E. Steam B. Co. Sewer Brick.	2.25	3.93	8.00	34.20	114,000	282,600	3,263
8704	No. 6. N. E. Steam B. Co. Light Hard.	2.44	4.16	8.33	34.65	67,000	159,300	4,592
8705	No. 7. Nyatt Brick Co.	2.28	3.58	7.29	28.35	98,000	209,900	7,404

I consider the above tables of great value to the building community. We are indebted to the enterprising firm of Norcross Brothers, who caused the above tests to be made, for much valuable information. By their great desire to know the strength of materials, and by the many precautions they take, they have gained an enviable reputation as being most thorough builders.

From exhaustive tests made during the building of the Allegheny County court house and tower, the tower being three hundred and twenty-five feet high, something over one hundred feet higher than Bunker Hill Monument, it was ascertained that the strength of brick built in walls or piers is very nearly one third of the crushing strength when crushed between smooth surfaces or imbedded in plaster; so that, in work where it is necessary to be near the margin of safety, it may be assumed that well-laid brickwork will carry in a wall one third the crushing strength of a single brick. In some parts of the above mentioned tower the brickwork carries twenty-four tons per square foot.

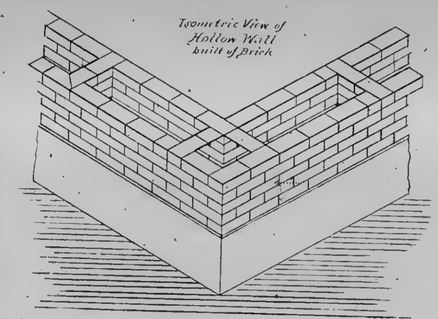
We also have other authority, taken from a book published by Frank E. Kidder, C. E., in 1892. On page 171 we find the following table:

	Strength of Masonry. per square inch.	
Brick (common) Eastern,		10,000
" (best pressed),	" " "	12,000
" (Trautwine),	" " "	770 to 4,600
Brickwork (ordinary),	" " "	300 to 540
" (good, in cement),	" " "	450 1,000
" (first-class, in cement),	" " "	930

Take, for instance, from the above table, "Brickwork (good, in cement)," using the lowest figures, 450 pounds per square inch. Assuming the weight of brickwork to be 112 pounds per cubic foot, it would require a brick column one foot square and 580 feet high to crush the brick at the bottom.

Taking one brick 3¾ by 8 inches which gives us a surface of 30 square inches, and multiplying this by 450, we have the sustaining strength, 13,500 pounds.

Now if we should lay one brick upon another to a height of 100 feet, we would have 500 brick with a weight of 2,000 pounds, thus leaving us 11,500 pounds to carry the load.



In a 16-inch hollow wall 10 feet long laid with the solid bonded wyths of brick, 30 inches from centre we have 1,080 square inches of surfaces. Multiplying this by the lowest number of the seven Rhode Island bricks tested, 4,492, we have 4,851,368 pounds, or 2,425½ tons, as our sustaining strength.

A hollow wall 10 feet long and 50 feet high contains 8,500 brick, with a weight of 34,000 pounds or 17 tons. Five hundred feet of flooring and roof at 25 pounds per square foot equals 6¼ tons; weight snow at 15 pounds per square foot equals ¼ ton; required by Boston ordinance for loading of floor, at 75 pounds per square foot, equals 15 tons; total, 39 tons. On deducting the 39 tons from the 2,425½ tons, we have 2,386 tons of additional strength. This is certainly enough to make it secure beyond all doubt.

If, instead of using the 16-inch hollow wall, we had used a 12-inch solid wall of the same height and length, it would have required 2,570 more brick, giving us 5½ tons additional weight on our foundations.

In using a hollow wall we gain many advantages, aside from the less weight and number of brick.

First. The hollow wall stands on a sixteen-inch base, while the solid wall has a twelve-inch base, making the former much the stiffer wall.

Second. We have a much dryer building, and one that is cooler in summer and warmer in winter; and frost will not appear on the inside of the wall, as is frequently seen on solid walls.

Third. The vacuum in the wall may be used to ventilate the cellar, and also to receive a pipe to conduct off the water.

This was done in the residence of the late George Crompton, of Worcester, Mass., and has never needed repairs.

Fourth. A hollow wall will stand fire much better than a solid wall.

This is shown in the Ashburnham Academy, where the entire woodwork was burned away, leaving almost the entire hollow wall standing erect.

In my practice as an architect I have built a great many buildings in which I have used the hollow wall. Some of these were very large and tall buildings, as the Congress Hall of Saratoga, N. Y., which is in part seven stories high. I have used this wall in many dwellings, schoolhouses, stables and mills, all of which are standing as firm as the day when they were built.

All the above calculations are based upon good materials and good, thorough work. When these are obtained I claim that the hollow wall is much the best, and that buildings constructed with them are the most desirable to live in. I hope that the city authorities will soon change the ordinances so that we will not be compelled to put in more material than is necessary, to the injury of the building. I would rather pay for the extra brick and then leave them out, than to put them in; for the thicker the wall the longer it will retain the dampness.

A reliable architect made a statement before a city committee that he had seen a candle blown out through a solid brick wall

twelve inches thick. In fact this was done before the Institute of Architects at Albany.

The apparatus used consisted of two tunnels placed one on each side of the wall. The connections were made thoroughly tight so that no air could escape. The candle was placed close to one, and some one blew in at the other. The candle was extinguished through twelve inches of solid brick. This experiment confirms the fact that dampness will penetrate a solid brick wall.

I have often asked the residents in houses built with the hollow wall if it is ever damp enough on the inside to cause mildew or mould, or the swelling of the woodwork. This question has invariably been answered in the negative, thus proving the superiority of the hollow over the solid wall.

An example of this is seen in J. G. Clark's house in the city of Worcester, which had been closed and without fires for over a year. At the end of that time there was not the slightest appearance of dampness on the interior.—The Brick builder.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

THE tendency of modern architectural practice, as of many other pursuits, is towards centralization in the hands of the best organizers—men who have, with other necessary qualifications, the ability to secure business and to dispatch it with such facility as to leave them free to devote a large share of their time to securing business. Ability of his kind consists of a combination of talent and training for what may be called the business side of the profession. With some there is little development of this faculty. While with some the possibilities in this direction are extremely limited, with others they are neglected. Every architect's assistant who does not wish always to remain such, should be awake to the necessity of studying how to do business. The peculiarities of every transaction he has a chance to observe, should be carefully noted and analyzed. The study of human nature and the adaptation of onesself to his surroundings, so as to be in touch therewith, is most important for the purpose mentioned. Next to this, nothing is more helpful than a good knowledge of the best methods in general office work. A habit of independent thought and a reasonable degree of self confidence should be cultivated. Students and young architects should not be satisfied with learning how to design and build in an artistic and practical manner. To be successful they must learn to handle the necessary business transactions with promptness and good judgment.

THE 16th and 17th of January is the date fixed for the annual convention of the Ontario Association of Architects. This convention, the arrangements for which are already far advanced, gives promise of being one of the most interesting and important in the history of the Association. The advisability of again bringing forward at the approaching session of the Provincial Legislature the proposed Bill to amend the Act of Incorporation of the Association, will be fully considered at this meeting. The opinion largely prevails that no more favorable opportunity of pressing the measure is likely to be afforded during the term of the present House. It is proposed to exhibit at this convention by stereoptican drawings or photographic views of buildings designed by members of the Association with the purpose of eliciting an exchange of friendly criticism. An invitation has been extended to the members to contribute drawings and photographs of their work for this purpose. The result of this new departure will be eagerly awaited, and we cherish the expectation that it will prove to be a most valuable feature of this and future meetings. Papers are promised from Prof. Coleman, of the School of Practical Science, on Building Stones; from Mr. C. H. C. Wright, Lecturer in Architecture, School of Practical Science, on Cements, based on original tests; from Mr. John Langton, Electrical Engineer, on Electricity Applied to Buildings; from Mr. Hamilton McCarthy, Sculptor, on Sculpture, its Relation and Application to Architecture; an illustrated paper on Architectural Rendering, by a student of the School of Practical Science, and four short papers on subjects not yet specified, from members of the Association. From the foregoing it will be seen that a programme of unusual interest is being provided. In order that the convention may be an unqualified success, it is required that the members of the Association should support it by their presence.

MR. Richard A. Waite, of Buffalo, is reported to have said to a Montreal reporter that he had been requested to examine the Montreal Street Railway Company's new building and give expert testimony concerning the cause of its failure, but had declined on account of professional reasons. Mr. Waite and the profession are both to be congratulated on this refusal to reap a personal advantage by transgressing the ethics of the profession. What a pity that Mr. Waite was not as well grounded in professional ethics prior to the erection of the Ontario Legislative Buildings!

IN a reference last month to the importance to the contractor of a knowledge of concrete construction, the promise was given that some formulas for work of this character would be published in the present number. This promise is to a large extent fulfilled in the excellent paper on "Concrete Construction—its Practical Application," by Ernest L. Ransome, printed elsewhere in this issue. In this paper the treatment given the subject is more comprehensive and thorough than in any single treatise which has yet come under our attention. Notwithstanding there are some phases of the subject which are not touched upon, and which will be considered on a future occasion.

THE plastic character of terra cotta naturally makes it a favorite building material. A recent writer has pointed out that out of this fact threatens to spring its indiscriminate use. Before the stamp of the artist can be exhibited on stone or marble, skill and labor, in no small degree, is required, but "terra cotta leaps forward to the modeler and, meeting him almost half way, realizes at once the grandest and broadest conception with an ease equalled in no other material." The danger will be to overload with ornament, and the prediction is that if this tendency is permitted to grow that the good service that terra cotta may do in building construction will be seriously marred and a distaste may be created against it that will destroy its usefulness.

ARCHITECTS, and especially members of the Architectural Associations, who may be desirous of promoting a high standard of professional ethics and of seeing the profession held in public esteem, should endeavor to make it perfectly clear that unprofessional conduct, wherever found, will be discountenanced. The Associations should not hesitate, if necessary, to discipline their members. If commissions are accepted from supply men or contractors, if work is undertaken at cut rates, or if unfair means be used to secure it in competition or otherwise—if in short disreputable practices of any sort are resorted to, it should be made plain that the person practising them has no standing among his brother architects. If wrong methods are allowed to pass unnoticed by reputable members of the profession, the public cannot be expected to know who are the reliable architects or that there is any difference as between one architect and another until they learn the fact by some disagreeable and perhaps expensive personal experience. The same is true of contractors. They should make a clear distinction among themselves, as regards those who are entitled to be known and dealt with as competent and reliable contractors. Instance, the question of responsibility. The contractor who pays one hundred cents on the dollar and is responsible in case of liability through accident to an employee, often has to compete in tendering with men who have no financial responsibility whatever. If the Employer's Liabilities Act is a just measure, why should not contractors be licensed? Responsible contractors should likewise use every legitimate means to make supply firms feel the necessity of strict terms and restriction of credit within safer lines. In tendering it should be made a condition that no tender should be considered binding until the contractor making it has had opportunity of knowing whose are to be the other accepted tenders, as he knows to begin with who is to be the architect. By this means it could be made much more difficult for men who inflict a loss on almost everybody with whom they come into business relations to secure contracts.

IN another part of the present number is printed the plan of a proposed organization to be known as the "Chicago Municipal Improvement League." The purpose of this organization is to secure for the city of Chicago "such an arrangement, design and adornment of its public buildings and grounds, streets and boulevards and other public works as shall most contribute to the convenience and enjoyment of the public, shall stimulate an appreciation of art, and give to the city a fit expression of its greatness." These objects are identical with those mentioned by Mr. A. T. Taylor, F. R. I. B. A., of Montreal, in the paper which he recently presented to the Province of Quebec Association of Architects, wherein he advocated the appointment of a committee of artists, architects, etc., to supervise the erection of public monuments, the laying out of public squares, etc. Referring to the Chicago League, to which we directed his attention, Mr. Taylor, writes as follows: "My idea was a little more modest than the Chicago organization, at least to begin with, but which would ultimately expand to embrace the wider objects. If we could get this Advisory Art Committee appointed to which all city art matters would be referred by the city authorities in all the large towns and cities of the Dominion, it would be a great step in advance. I am in hopes of getting our Association here to petition the Council in favor of such a scheme for our city. ..... The Dominion is, I think, quite ripe now for an increased attention to the art side of its national life and progress, and looked at even from its lowest point of view—that of the dollars and cents aspect—it would pay, for whatever adds to the beauty and attractiveness of our cities and towns would tend to draw both people and money; but I prefer to put it on the higher ground of culture, art training and actual enjoyment of the people themselves." We are pleased to observe that since the above was written the Province of Quebec Association of Architects has adopted a resolution embodying Mr. Taylor's views. The Ontario Association of Architects might profitably we think give some consideration to this subject at its approaching annual convention, and it is to be hoped that the initiative taken by Montreal will be followed by Toronto and other principal cities and towns throughout the Dominion.

ONTARIO ASSOCIATION OF ARCHITECTS.

A GENERAL meeting of the Ontario Association of Architects was held in the Lecture Room of the Canadian Institute on Friday evening, Nov. 16th.

The programme consisted of a Lecture on Statics by Mr. C. H. C. Wright, B. A. Sc., of the School of Practical Science.

With the aid of some simple apparatus and a series of prepared diagrams a demonstration was given of all the fundamental principles involved in "Graphic Statics" and their direct application to framed structures such as architects constantly meet with in practice.

It was also shown, that by the use of drawing instruments alone, and an average knowledge of mathematics, that the stresses in even complex structures due to exterior loading, could be readily determined when once the leading principles were fully understood.

In the discussion that followed, some of the architects present illustrated how nearly theory and practice agree in this respect, by examples from their own work.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

UNDER the title "A Gift to Quebec Architects," the Quebec Telegraph of recent date contained the following:

"Public attention is directed to the magnificent tableau or exhibition at Lavigne's music store, in Fabrique street. It is by Notman, of Montreal, and some three to four feet in length. It contains the portraits of some forty-seven of the architectural fraternity of the sister city and below each portrait is the name of the architect. The Quebec section of the Association of Architects of the Province of Quebec had last year or at a previous general meeting of the Association presented their confreres of Montreal with a similar tableau, photographed by Beaudry, of Quebec, but naturally of less dimensions, as it only contained the portraits of some twenty Quebec architects. The tableau at Lavigne's is as the French have it "*le retour du gateau*" and was presented by the Montreal section to the architects of Quebec, at the opening of the last general meeting of the Association at Montreal on the 5th of October last, when Mr. Baillairgé, of this city, was elected president of the Association for the ensuing year of 1894-95."

The works of the Owen Sound Portland Cement Co., at Shallow Lake, Ont., are again in operation, and are turning out 125 barrels of cement per day.

THE BYSTANDER.

GIVEN the opportunity recently of spending a pleasant hour with Mr. C. H. C. Wright, Lecturer in Architecture at the School of Practical Science, Toronto, the value of a technical course in education was impressively forced upon the Bystander. The high character of the school system of Ontario has long since passed into a proverb. Perhaps, sometimes, because of this excellence, the tendency is to overrate the system, or rather to forget that with its excellent features also come a few defects. Citizens who, like the writer, have little ones at school, are not without opportunity of seeing where these defects exist. However, it is not the intention of the Bystander to write an educational article. One of the encouraging features of the educational system of the present day, confined not alone to Ontario, but embraced by other provinces of the Dominion, is the growing attention given to the practical side of life. In a country where few are born with a silver spoon in their mouth, and work is the lot of the many, there is need that what the boys and girls learn at school should be of service to them in the everyday callings of life, and not something to be learned only to be forgotten. The School of Practical Science, so well domiciled and equipped between its walls of red brick in the Queen's Park, is doing its full share along these lines, as are also the Schools of Manual Training and Technology that have their place in other towns and cities in Ontario, Quebec, and elsewhere.

× × × ×

The conversation with Mr. Wright took a "shop" turn, and in a direction in which, no doubt, many readers of the ARCHITECT AND BUILDER are interested. The Bystander had recently read with some care, and not without astonishment, an article written by Mr. Cecil B. Smith, one of the teachers in the technical building of McGill College, Montreal, on the question of Portland cements. The increasing uses of Portland cement makes this a subject of importance to architects and contractors. Mr. A. Blue, director of mines for the Ontario government, is authority for the statement that as between the years 1880-81 and 1892-3 the imports into Canada of Portland and Roman cements have shown an increase of nearly 600%, and as between 1880 and 1890 the number of establishments manufacturing cement in Canada have grown from 9 to 19, and on the basis of values the manufactured cement in Canada increased from $91,658 in 1880 to $251,175 in 1890. As Mr. Wright remarks, Portland cement is being used for many purposes to-day that would not have been dreamt of so much as a decade ago. Everyone is aware by ordinary observation of the extent to which cements are now used in road building. The intelligent agitation of late years, the country over, for good roads, must receive credit for a large proportion of this increase, though in this respect newer countries are only following the example shown in the construction of Roman roads in Europe 2000 years ago, where it was made an essential of road building that the foundations should be laid good and strong. Not only in roads, but for other purposes, where strong and durable foundations are required, concrete to-day holds a first place. Mr. Wright says that piers of bridges are now being constructed of concrete and are found to possess many advantages over masonry. The price, of course, is one consideration, but with this goes equal strength, and satisfaction to contractors in the work of construction. Taking a forward look from this standpoint it can be readily understood that the future must show a large development in the manufacture of cement, and this is good reason why care and attention should be given to a study of the question Mr. Smith's criticism is to be welcomed on this account, notwithstanding that it is at fault in important particulars.

× × × ×

Mr. Smith takes the ingenious position of regretting that the Canadian government has recently contracted for 11,000 bbls. of Portland cement of foreign manufacture, intimating in the next sentence, however, that he does not well understand how, under existing conditions, the government could have pursued any other course. He is quite correct in stating that the Canadian output of Portland cement has been a long way short of meeting the demand in Canada, but this does not justify a protection government in deciding squarely against the home manufacturer. In the government specifications English cement is specially called for, a barrier at once to the Canadian manufacturer bringing his cement into competition with that of the foreign manufacturer in the construction of public works. The Bystander has been pleased to learn, however, that the government is likely, at an early date, to abandon this invidious distinction between the home and foreign article, and that before long in their specifications it will be an open matter, whether the one or the other cement shall be used. This fact of itself will have an influence in meeting the conditions that are bemoaned by Mr. Smith. Of course, it is true that the manufacturers of cement in Canada are yet unable to nearly meet the demand that exists for cements in this country, but time and fair play will remedy the difficulty. This is to be remembered, that the manufacture of Portland cement in the Dominion is of recent origin. The Rathbun Co., the Owen Sound Portland Cement Co., and the English Portland Cement Co., of Milbank, have spared no expense and care to perfect their equipment in order that, first of all they should satisfy themselves that they could manufacture a cement that would compare favorably with the imported article. This, as will be shown, the Bystander believes, further on, despite Mr. Smith's criticism to the contrary, has been accomplished, and the track is clear for a large development in the manufacture of Portland cements in Canada. Further, let it be remembered that Canadian manufacturers have not alone been compelled to meet a very great increase in demand within their own country, but also to keep pace with this demand during the initial days of manufacture.

× × × ×

The gravamen of complaint from McGill College is that there is a manifest lack of uniformity in grinding and burning in Canadian cements, and Mr. Smith submits certain tests he has made in verification of this statement. He adds as a comment to a test of three samples of a No. 1 brand that had been selected: "That such a tremendous variation should exist is enough to cripple the industry until this is remedied." These, he says, are samples obtained, not from the manufacturer, but from dealers, taken from the article as placed on the market, which he argues is the only satisfactory test that can be applied. A snap verdict, where care has been taken to place the best specimens in the hands of the tester, cannot be accepted as a fair test of the general character of cements. "Let us grant," said Mr. Wright, "in discussing the point, that this is the proper method of arriving at the real character of the cement regularly in use by contractors. But what is the usual practice and experience? Mr. Smith writes as though this 'tremendous variation' was applicable only to Canadian cements, and the inference is that imported cements are not faulty in this respect. Ask some of the contractors and engineers, who have occasion to use the imported Portland cement, what is their experience. It is notoriously true that this variation exists in all cements, there being different conditions that seem to tend to this want of uniformity." It is only two years ago that a single shipment of some 4000 or 5000 bbls. of English cement was sent to this country, which, though bearing the brand of a reputable maker, was found to be of a very indifferent character. What was the history of this particular shipment? English manufacturers had been in the habit of making up large quantities of cement for shipment to South America, where the tests were not so severe. A financial crisis occurred in that country and manufacturers were left with heavy stocks of this grade of cement on hand. They had to dispose of these somehow, and part came to Canada. "Just take another illustration," continued Mr. Wright. "Let me draw your attention to the conditions set forth by an American concern in its specifications where Portland cement is called for." The Bystander was here shown the printed specifications in which it was directly stipulated that the cement to be used should be either White's English Portland cement or a French manufacture, but it was just as clearly stated in the conditions that these cements were not necessarily to be accepted without first undergoing certain tests. Evidently these people had learned that the particular label of a foreign manufacturer did not always insure a cement that was uniform in character. Only within the past month efforts have been made by English manufacturers of Portland cement to adopt means to prevent the placing on the market of certain qualities found to be exceedingly faulty in character.

× × × ×

So far as Mr. Smith is desirous of having produced in Canada a cement of "uniform fineness and strength, which will answer severe specifications," he will have the support of all who wish

well to the manufacturing interests of the Dominion. "For my part," said Mr. Wright, "I am of one mind with my Montreal congener in this matter." But where does the fault in grinding rest to-day? Chiefly with the consumers, who are satisfied with a low grade of grinding, and in no inconsiderable degree the engineers of the country are blameworthy. The truth would seem to be, from the fact, perhaps, that Portland cement has only come into extensive use within a few years, that Canadian engineers have not any more than commenced to give this matter the study and care that it merits. Consumers are satisfied, in many cases, with a cement that will stand no higher than a 20 % test of a No. 50 sieve. Nothing more than this is frequently called for in specifications from contractors and others. When the consumer is satisfied, the engineer is not likely to insist on a higher standard. Here it is that Mr. Smith and Mr. Wright believe that reform is necessary. And in this regard Canadian cement really takes a higher place than the imported article, perhaps sometimes to the prejudice of Canadian trade. Canadian manufacturers are ambitious to produce a good article, and will not, as is the case with some imported cements that come to this country, be satisfied with anything less than a high class test. A large proportion of English cements will not average a 10 % test, where, from data of tests shown, the Bystander by Mr. Wright, he is able to say that Canadian cements seldom fall below a 5 % test, whilst he has seen those that have run as high as one per cent. and others 2½% and 3%. In a paper on concrete construction, read at the annual convention of the American Institute of Architects, and published in this month's ARCHITECT AND BUILDER, a similar view of the grinding of cements is held. The manufacturers of Canadian cements are evidently holding up the true ideal and it remains for the engineers, rather than the manufacturers, to see that the severer test is insisted upon in all cases.

× × × ×

Many people are influenced by their environments and the Bystander has thought that, perhaps, the natural habit of the good people of Montreal of taking an English view of matters has colored Mr Smith's diagnosis of Canadian cements and caused him to write in a severer tone than would otherwise have been the case. Then from a Montreal point of view there is the local influence that comes from the desire to maintain at its best the shipping interests of the metropolis, and it is well known that these obtain no inconsiderable share of trade through the importation of foreign cements. Let Canadians occupy the home field as manufacturers of cement, and this line of traffic will suffer. However this may be, it may be expected, as the subject is more fully entered into that Mr. Smith will see that there is little, if any, material difference between English and Canadian cements, while the advantage is really on the side of the former. Rapid strides have been made within the past ten years in this branch of manufacture in the Dominion and continued progress during the decade ahead is to be expected. Readers will be pleased to know that at the forthcoming annual meeting of the Ontario Association of Architects Mr. Wright will read a paper on cements and submit several tests.

BUILDING IN THE NORTHWEST.

In a lecture delivered recently at the Y. M. C. A., Winnipeg, entitled "Architecture, or the Art and Science of Building." Mr. Geo. Browne, architect, of that city, thus refers to the improvement which is taking place in architecture and building methods in the Northwest:

"When I came to Manitoba in the spring of 1879, there were no buildings of any importance, and the wigwam of the Indian, and the log house of the pioneer were seen on every side, while the frame buildings were not numerous off Main street, and when I returned to the city in December, 1881, to reside, architecture was still in a primitive state. Architects and builders seemed to have little or no knowledge of the proper methods to pursue in order to erect buildings suitable for their purpose, the climate and the place. Since then, however, considerable knowledge has been gained, and progress made, both as to the proper methods of construction and design. Time and experience have taught the necessity of avoiding many things which in the early days were considered quite correct; or, to use the old phrase of the boom days, "good enough."

The now historical boom period did more than anything else to retard the erection here of improved and substantial buildings. Money flowed so freely that men lost their heads, and in the excitement of the hour gave no attention to their comfort or to the proper improvement of their habitations, imagining that their residence here would be brief, and as soon as they digested the numerous flies then buzzing around anxious to walk into their parlor, they would reverse the advice of Horace Greeley and go east. But when the boom burst they awoke to the fact that the flies had gone east instead of themselves, and left nothing but mortages to be paid off, and old, ricketty buildings to fix or pull down. The impression became general that a reform would have to be made in the methods of building then followed, and the result has been that the objectionable plan of setting large timbers on the ground for a foundation to receive the superstructure has been abandoned for the common sense stone foundation. At one time it was considered necessary for the safety of the building to build the foundations on piles, or two or three thicknesses of 2-inch plank laid cross ways or diagonally and spiked together, but both have been found unnecessary and expensive, and only on rare occasions are resorted to, concrete and broad footing stones having been found quite sufficient to carry our heaviest buildings on the blue clay, provided the latter is properly drained. Footings of broad stones without concrete are sufficient enough to carry an ordinary building. Stone foundations should be coated well on the outside below the ground line with hot tar and pitch or Portland cement to keep the damp out of the wall and cellar, and where expense is not an object, the foundation wall should be lined on the inside with 4-inch brick with 2-inch air space.

I am frequently asked which I consider to be the warmest, a house of solid brick, a frame house or a brick-veneer house. I believe that the three kinds are equally warm if properly built and attention is paid to details, which seem but trifles to the average workman, but which play a very important part in adding to the comfort of the inmates. One is to build in properly the door and window frames so that when the wood of which they are constructed shrinks, they will be air-tight. Another one is, in the case of a veneer house, to fill in the space between the boarding and brickwork, solid with mortar, and in all houses to have two air spaces in the exterior walls, formed by putting on the inside of the walls 1 by 2 inch strapping, lathing and plastering one coat, commonly called back-plastering, which should go, in every case, from the ground floor joints up the walls and rafters and between the joints, practically making an air-tight jacket of plaster for the building.

If the house is to be heated with hot air, the cellar should not be less than 7 feet 6 inches in the clear, to allow the pipes to have a good incline. The furnace should be placed so that the pipes will be of equal length and as short as possible. Long pipes interfere with the proper working of the apparatus and are of little or no benefit to the rooms to which they lead. Return pipes are necessary to draw off the cold air from the rooms and create a vacuum for the hot air to fill.

People complain of the shrinkage that takes place in the woodwork of their houses, and attribute its cause to its not having been properly seasoned before being fixed in position, and while in some cases this may be the correct reason, in others it is owing to the wood absorbing the moisture from the plaster, for the wood finish is, as a rule, rushed on before the latter is dry, and by that time the chilly weather has set in, the furnaces started and a hot blast thrown on the wood work and severely testing it.

The unusual dryness of our climate is also responsible to a certain extent. I have known wood works, after having been in for two years in the east, to fall to pieces after being here only a short time.

Owing to this defect, which we cannot easily overcome, I never paint my interior work more than two coats the first year, leaving the third coat to be applied the following year, after the work has been rubbed down and the cracks and open points puttied up.

The architecture of our city is now in a transition state; the wood, brick-veneer and galvanized iron age is passing away, and is being succeeded by the stone, brick and copper age, our capitalists recognizing that it is poor economy not to build for the future as well as the present. As an illustration I will point to the building in course of erection for Wesley College, which shows a greater advance in architecture than any building yet erected in Manitoba. The college board are to be congratulated that their building can be viewed from every side with pleasure, and that they have avoided the common error of making the building Queen Ann in front and Mary Ann behind.

I sincerely trust that many months may not elapse before I shall have the pleasure of congratulating you on the completion of your new and permanent home. I think that citizens of Winnipeg, and also their country cousins, should do their utmost to reward your efforts with a building worthy of the noble cause in which you are co-workers.

What is termed a "ventilating window" is now being adopted in some of the barracks and other public buildings in France. It consists in employing two panes of glass for one, with a space between them, and their length so curtailed, one on the lower side, the other on the upper, that the air comes from the outside, passes between the panes, and enters the room. Such a window is, of course, only required in one part of a room, preferably near the ceiling.

STUDENTS' DEPARTMENT.

AN ENQUIRY.

TORONTO, Dec. 1st, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—I am troubled in my mind about a house which is just about completed on Lowther ave., this city. The design, particularly the front elevation, is different from anything I have seen in a similar situation. I should therefore like to know something of the reasons for its peculiarity. Toward the street the windows are few and small, giving it an appearance far from cheerful. They are larger in the rear. I have read of houses of which it was necessary to understand the plan in order to appreciate the design. Perhaps this is an instance of that kind. I have seen it partially promised, or at least proposed, that the O. A. A. would hold open meetings with illustrations and friendly criticism and discussion of some works. I would be delighted to see and hear the subject referred to treated in this way. Is there any probability of such an opportunity being afforded during the present winter?

Yours faithfully,

INQUISITIVE STUDENT.

A WATER-COLOR CLASS FOR STUDENTS.

TORONTO, Dec. 11th, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The endeavor has recently been made to establish a water-color class for architectural students in this city, under the exellent instruction of the well-known artist, Mr. C. M. Manley. Notwithstanding the extremely moderate figure at which Mr. Manley consented to give his services, great difficulty was experienced in getting the half dozen members necessary to form the nucleus of the class.

In the spring of 1893 a water-color class numbering some eight or ten members, was formed, and made good progress, but most of the members upon whose energy its success depended are now in the United States. Sketch clubs have likewise been founded, with what success we all know. I think it is the deprivation of a few winter Saturday afternoons, including the foregoing of hockey-clubs and various other social attractions that keeps the majority of students from joining. As architectural students, choosing a profession in which not only the trades, but also the arts are involved, why should we hesitate for a moment in grasping every opportunity presented to us for self-improvement?

Sincerely yours,

STUDENT.

ARCHITECTURAL STUDENTS.

Book work and practical work are two of the relative factors in the student's life; but for some reason or other, says the Building News, they are generally divorced. Many a student thinks he can learn everything from books. The recent remarks of a medical authority to students in that profession are applicable to the architectural student. The elementary textbook ought to be used as the skeleton of his knowledge; the student ought to endow it with the tissues and life from his own personal observation, by practical school courses and visits to buildings. A mere dry study of textbooks is of little value, except to furnish the mind with names and definitions, and yet the ordinary student regards the textbook in the light of something to be read through, and committed to memory as quickly as possible. No wonder the pupil undervalues the textbook, and looks upon it much in the same manner as the schoolboy does his Murray or his Eaton Latin Grammar. They are looked upon as "dry as dust" manuals, and the more elementary they are the more difficult they are to grasp and comprehend. Instead of being used as a "skeleton of knowledge," which they simply are, to be clothed by his own experience, the student cannot see any use or value in them, as they do not supply his needs. But the student of a practical order of mind, who has served his time in an office, can utilize the elementary textbook; he reads into it his own experience, and he begins to read it with some interest. A good advice given by an eminent physician to his class is to write his own textbook by grafting his practical work on to an elementary manual, and to revise his knowledge before entering for an examination by the light of a first class textbook. Every student can do this; if he has any love for his work at all, he will take an interest in filling up the outlines and dates of a manual on styles with his own notes and sketches, and his scientific textbooks with remarks of his own derived from practical knowledge, or from other authors. The Institute rightly insists on the necessity of making reading thorough by supplementing it by the taking of notes and sketches, and by information under various heads from different authorities. The continuous use of a note-book is enjoined on the student, in which he should write down, in his own words, the principal part of the books under study, and also supplement these notes by sketches from all available sources (notes on one page, sketches on the opposite page). The accurate sketching of old work in plan, elevation, construction, and detail from memory is equally valuable, thus bringing eye, brain and hand into exercise. In this way the student can be made to enter into the spirit of the art. The note and sketch book are the only true tests of the student's knowledge; they serve to indicate the extent of the knowledge he has made his own from lectures and reading and observation, and serve to mark him off from those who pursue the course-and-cram system, and desire to become architect in name only. We are inclined to think, despite the advice of teachers at official head-quarters, that the "course-and-cram" system is now most in favor amongst young men who desire to assume the *role* of architect or engineer. Like the clincial work of the medical student in the hospital wards, the practical work on building must go hand in hand with books and lectures.

Perhaps there is another distinction between the two aspirants we have been considering, and one that lies deeper than methods of study. The novice who is in such a hurry to take the name of architect is often a more receptive man than he who is in earnest to prove his qualifications and credentials. He learns by rote quickly, has a capital memory, and, with the help of a little "coaching," is sure to pass any examination. It has been pointed out by all authorities on teaching that the receptive man quickly learns and benefits by teaching, which only arouses opposition in the critical man, and this explains the reason why so many of those who have passed examinations with credit frequently fail to exhibit any talent in actual practice. In every profession there are examples of this fact; but in architecture we find designers of very feeble buildings able to go through their examination with conspicuous credit. Between the critical faculty necessary to select good forms and to arrange plans upon logical data, and the mere receptive ability to collect facts and work out formulæ, a great gulf is fixed. The one order is preceptive—it can discriminate between good and bad, can think out a problem of design, while the other can only gather and grope its way between conflicting opinions. The first can invent, the other only collect and classify; hence we find that copies and poor compilation of existing buildings are the rule rather that the exception.

CHARACTERISTIC FEATURES OF HOT-WATER HEATING.

FIRST. The ability to produce a gentle warmth with a low fire. The temperature of the water may be raised to 100 degrees for the chilly damp days of September and May, 140 degrees for the cold air of October and April, and 180 and 200 degrees for the cold winter months, the amount of heat being regulated from day to day as the season demands.

Second. Should the fire be unintentionally neglected, the water will continue to circulate and give off its heat as long as any fire remains in the boiler, or warm water in the pipes.

Third. Hot water may be regulated to meet any ordinary changes of temperature, and therefore there is no excuse for overheating on mild days. This point, however, may be urged for steam where the boiler is provided with modern automatic regulating appliances.

Fourth. The valve or radiator may be partly closed, which will retard the circulation and cool the radiator down to any desired temperature.

Fifth. The circulation of hot water is invariably noiseless, the pressure is uniform, the heat is clean, mild and delightful, and with intelligent management great uniformity of temperature may be obtained throughout the house.—Plumbers' Trade Journal.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The Building Inspector has condemned the new St. Johns church in course of erection at the corner of St. Catchrine and Cadieux streets. The exterior wall, built of stone and faced with brick, age said to have been found to be so defective in workmanship, that for the safety of pedestrians, the architect, Mr. Geo. Mann, has been compelled by the Inspector to have them torn down. This is proving a difficult task for the workmen, as an effort is to be made to preserve the roof, which was already in position when the order to reconstruct the walls was issued.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

At a general special meeting of the members of the Association held on Thursday, the 6th inst., to consider the proposed amendments to the by-laws, the following members amongst others were present:—Messrs. A. C. Hutchison, A. T. Taylor, J. Nelson, A. Raza, H. C. Nelson, J. Perrault, J. Venne, M. Perrault, J. Wright, J. Z. Resther, A. H. Lapierre, Geo. W. Wood and J. R. Gardiner. It was proposed, first: by Mr. A. C. Hutchison, seconded by Mr. J. Wright, that the following words in the third, fourth and fifth lines of section XI of the By-Laws, viz: "collect all funds and hand them to the Treasurer, taking his receipt for the same," be struck off and in line 8th of the same section to omit the words "receipt for them to the Secretary;" to add to section XI the words "the Treasurer shall also furnish to the Secretary at the close of each year, a list of the members whose subscriptions have been paid." To strike out the words "to" at the beginning of the 8th line and to substitute "to collect and." Carried.

Second—Proposed by Mr. W. E. Doran, seconded by Mr. Jas. Nelson, that section V of the By-laws be amended by inserting after the word "separately" of the fifth line of said section "the retiring president shall be the premier member of the Council", then after the word "the" actually following "separately," to add the words "other five" to read as follows: "The other five members of Council may be balloted for on one paper." Carried.

Third—Proposed by Mr. A. T. Taylor, seconded by Mr. J. Z. Resther, to change section VIII of the By-laws to make it read as follows: "The Council shall appoint each year a board of six examiners who shall," etc. Carried.

Lastly—It was proposed by Mr. J. Z. Resther, seconded by Mr. A. T. Taylor that the following be elected as honorary members of the Association: The Lieutenant Governor of the province, the Prime Minister and the Minister of Public Works of the province, the Mayors of Montreal and Quebec, the Honorable Sir Donald Smith, the Honorable J. A. Drummond and Mr. R. B. Angus. Carried.

It was resolved that the President of the Association be instructed to issue a circular to the members giving them notice of the above adopted amendments.

It was also proposed by Mr. A. T. Taylor, seconded by Mr. A. Raza, that the Association propose to the City Council to have a special committee formed for the embellishment of the city. Carried.

The first of the monthly dinners, for the winter, of the Association was held on Tuesday, the 11th inst., at the City Club. After the dinner the members met in their rooms, New York Life Building, when the following paper, prepared by the President, Mr. Charles Baillairgé, F. R. S. C., was read:

A QUICK AND EASY WAY OF GETTING AT THE WEIGHT OF IRON SCANTLINGS, GIRDERS, COLUMNS, ETC.

Bear in mind that a cubic foot of iron weighs 480 lbs, therefore an inch thick and foot square is 40 lbs., or one twelfth of the cube foot. Therefore also half an inch 20 lbs., ¼in. = 10 lbs., ⅛in. = 5 lbs., 1-16in. = 2½ lbs., 1-32in. 1¼ lbs. You need not try to remember these; as by a quick mental process you can start with the foot or inch and in less time than it requires to write this, halve the inch, then halve the half inch, then the quarter and so on.

Now if your scantling be 3in.x1in. and as 1in. a foot square is 40 lbs., the 3in. bar will be 1-4 of 40 lbs. or 10 lbs. If your bar is 4in. wide or ¼ of a foot, you will have ¼ of 40 lbs. or 13⅓ lbs. For 1-2in. bar or 1-4in. or ⅛in., etc., the same process holds good. For instance, a bar 1-4in. thick and 2in. wide will be the 6th part of a square foot or the 6th part of 5 lbs., or 5-6 of a pound, since 5 lbs. x 6-30 sixths and 30 sixths divided by 6 gives 5 or 5-6 lbs., as just stated. Three inches by 1-4in. will be 1-4 of 5 lbs. or 1-4 lbs. and so on.

Now, take a bar 1 in. square, and since a foot inch is 40 lbs., the 1in. bar will be 1-12 of 40 lbs. or 3⅓ lbs., to the lineal foot. If the bar be 1 in. x 1 1-2 in., and as 1 1-2 is ⅛ of a foot, the bar will weigh 1-8 of 40 lbs., or 5 lbs., since 8 into 40 gives 5 times. And if the bar be 1-2 in. x 1 1-2 in., it will be ⅛ of 20 lbs. or 2 1-2 lbs. If the bar be 3 in. by 1-4 in. it will be 1-4 of 10 lbs. or 2 1-2 lbs., and if 1-8 in. x 3 in., 1 1-4 lbs. or the quarter of 5 lbs.

Say now your bar is ⅞ in. square, and as an attempt to divide 12 inches or a foot by ⅞ in. would lead to a more difficult or lengthy process, do it this way:—spread it over mentally into eighths of an inch. Thus seven times seven eighths = 49 eighths or 6⅛ inches in width of ⅛in. thick iron. Now take for 6 in. (half a foot) the half of 5 lbs., or 2 1-2 lbs., but there is still ⅛in. x 1½ in. unaccounted for, which being only 1-48 of the 2 1-2 lbs, may either be disregarded as a very small fraction of about 2 per cent., or if we wish to be more exact, and as it is mentally difficult, or even with pen or pencil to get at the 48th part of 2 1-2 lbs., reduce your 2 1-2 lbs. to ounces, giving 40 oz., and now you see that to the 2 1-2 lbs. arrived at as above, you have to add 0.83 of an ounce, or say 4-5 of an ounce, or even a whole ounce as, except for hundreds or thousands of lineal feet, the neglected fraction of an ounce would hardly cover the trouble of exact computation.

Apply now the process to iron 1 1-4 in. square; reduce the bar in imagination to 1-4 in. iron, when it will be 5-4 in. x 5 times, or 25 quarters of an inch in width, or 6 1-4 inches, or half a foot plus 1-24 of half a foot, and as 1-4 in. iron weighs 10 lbs. to the foot, the 6 in. in width will give 5 lbs., and as 5 lbs. = 80 oz., and as the 24th part of 80 oz. is 3⅓, (since 3 times 24 = 72 and 80 or ⅓ oz. over), therefore to the aforesaid 5 lbs. add 3⅓ oz., and the exact weight of the 1 1-4 in. square bar per lineal foot is 5 lbs. 3⅓ oz.

Again if the square bar be 1 1-8 in. or 9-8 in. and as 9 times 9-8 = 81 eighths or 10 1-8 in., and as 10 in. is the 5-6 of 12, therefore the bar will weigh per lin. ft. the 5-6 or 5 lbs. or of 80 oz., or 66 2-3 oz., but there still remains 1-8 in. to be accounted for, which just gives 5-6 oz. more, forming together 67 1-2 oz. or 4 lbs. 3 1-2 oz., say 4 1-4 lbs. nearly.

This last example may be more easily and quickly computed by taking the bar as so much of a foot of iron 1⅛ in. thick, or 45 lbs. to the foot, when we get for 1 in. 0.81 one-twelfth of 45 lbs., or 3¾ lbs., and for the ⅛ over add 1-8 of 3¾ lbs. or 1-8 of 60 oz. = 7 1-2 oz., together as before 4 lbs. 3 1-2 oz. or 4 1-4 lbs., nearly 3¾ lbs.

For computing the weight of sound bar iron or of solid posts or columns of circular section, the simplest way is to compute as square and then reduce. Well, geometry teaches that the area of a circle is .7854 of its circumf. scribing square, or that the area of any square is to be reduced to that of its inscribed circle by a multiplication of said area by the decimal fraction .7854, which is the area of a square of which the diameter is equal to one (1) or unity. These figures .7854 will be better understood as a percentage. Thus, the area of the circle is very slightly in excess of 78 1-2 per cent. of its corresponding square. Now, since decimal 76 is equivalent to three-quarters (3-4), we therefore have to take, to begin with, 3-4 of the weight of our square bar, which is best and quickest done by taking half of it and then half of that or a quarter of the whole. Now, there still remain to be added 3 1-2 per cent. to get at the full weight required. This 3 1-2 per cent., or more correctly $3\frac{54}{0}$ per cent., being multiplied by 7, we get (354 × 7) 2478, or very nearly 25; therefore the remaining figures 354 of the .7854 are almost exactly equal to 1-7 (one-seventh) of .25; therefore, by dividing the weight set opposite to the 25 per cent. or one-quarter of the weight of the square bar or scantling, we get the fraction to be added to the 75 per cent. already obtained to arrive at the comparative weight of the round scantling. Thus then we make unto ourselves the rule: to compute weight of round iron, calculate it as square, and then take one-half, plus one-quarter, plus one-seventh of one-quarter (1-2 + 1-4 + 1-7 of 1-4) of weight of square bar; this process being far shorter or more concise than that of multiplying by .7854, which would further require a reduction of the ounces or fractional portions of the weight to a decimal to allow of such multiplication.

EXAMPLE.

Suppose the weight of one lineal foot of a bar of square iron to be 5 1-2 lbs. Thereby the rule, the corresponding weight of the round bar, or weight of a round bar of same size, will be the half of 5 1-2 plus the 1-7 of this last or 1-8 × 1-16 or 3-16 lbs., together 4 5-10 lbs., lbs., or 2¾ lbs., plus the half of this, or quarter of the whole, = 1 3-8 lbs. or 4 lbs. 5 oz.

Otherwise, reducing the 1-2 lbs. to a decimal,

we get	5. 5	lbs.	or reducing again the
1-2 of which	2. 75	"	fraction of a lb. to decimals
1-2 of this	1. 375	"	5. 5 lbs., and multiplying
1-7 of this	0. 1964	"	by 7854
	4. 3214		39270
			39270
			431970
		or	432 very nearly,

which shows that the fraction 1-7 for the remaining decimal 354 of the .7854 differs from it by little more than one-thousand $\frac{1}{1000}$ of a pound.

Now, for cast-iron, it is true the weight of a cubic foot is only 450 lbs. instead of 480 lbs. for wrought iron; but as it is always safe in estimating in advance to be on the safe side, to make up for any omitted trifling items, I generally use same figures as for wrought iron; also because when contracted for by weight, the tendency is to give the casting as great a weight as possible, and even when the thickness asked for is not exceeded there is generally a slight allowance to be made for so much of the sand or core adhering forcibly to the casting and hard of removal.

Therefore for any straight work or rectangular, as for a girder, column or stanchion of square, rectangular, crucial or cruciform or box-like cross section; estimating the elemental components and putting them together will give the weight of a lineal ft., which into the length or height of the column or girder will give its total weight.

With regard to circular work, as of a cast iron column, the inner diameter added to the thickness gives the mean diameter and this taken 3 and 1-7 times gives the mean circumference or girth, which into the weight of a lineal ft. of the column under consideration, and this last into the length in feet, will be the total weight of the column.

For example, say we have to compute the weight of a column of which the outer diameter is to be 8 in., and the metal 7.8 in. thick, therefore, the inner diameter or base will be 6 1-4 inches and the mean diameter 6 1-4 in. plus ⅞ in., or 7 1-8 in. (or which is the same thing, the mean diameter is similarly arrived at, as the outer-diameter 8 inches, less the thickness of 7-8 in. = 7 1-8).

Now, diameter 7 1-8 in. x 3 1-7 gives 21 in. 3-8 x 1-7 of 7 1-8 in. or say 1 in.; therefore mean circumference = 22 3-8 in., say 22 1-2 inches, or 1⅞ ft. superficial. Now iron ⅞ in. thick = ⅞ of 40 lbs. = 35 lbs. (or iron 1-8 in. thick = 5 lbs. and 7 times 5 lbs. = 35) and 35 lbs. into 1⅞ times gives 65 ⅝ lbs. for foot lineal.

If it be required to weigh any irregular form such as a statue or piece of carving or scroll work, of which the cubical contents are unknown, the latter may easily be had by immersion of the object in sand or water in a cylindrical or rectangular box or tub of quick and easy computation, and a mere comparison of the height when just covered by the sand or water with the height of depth of the auxiliary material after removal of the object. Thus if the box be a foot square in cross section and the filling stand 3 feet high or deep with the object in it, and 2 ft. 9 inches after the object is removed, the cubical contents arrived at are a foot square and 3 inches in height or 1-4 of a cubic ft., or 120 lbs. If the object be hollow, it must of course be inverted in the bath, so the sand or water may fill the hollow space.

Or the weight of an object to be cast of any metal may be made known in advance by weighing the model of it inwood or any other material and by simple rule of three, comparing their specific gravities. And in like manner when the weight is known of any object, its cubic contents may be arrived at by a mere inversion of the terms of their proportion.

Thus of a shapeless piece of stone or wood or metal, the ratio of its cubical contents to those of a cubic foot of the material, from a table of specific gravities, will be the same as that of the weight of a cubic foot of the material to that of the piece to be computed.

In the foregoing mode of obtaining the cubical contents of an irregular figure by immersion in a vessel, if the vessel instead of being cylindrical or rectangular, has tapering or splayed side, or be the frustrum of a cone or pyramid, the contents must of course be computed by the prismoidal formula, which consists in adding to the sum of the areas of the upper and lower bases of the tub or vat four times the middle area (of which the factors are arithmetic means between those of the end areas) and multiplying the result by one sixth part of the depth or height.

MASTER PLUMBERS' ASSOCIATION.

At the annual meeting of the above Association held last week, the following officers were elected: President, J. Lamarche; vice-presidents, J. Date, A. Champagne and H. Paddon; secretary, W. Briggs; English corresponding secretary, W. Hughes; French corresponding secretary, J. Thibeau; financial secretary, J. C. Jacotel; treasurer, W. A. Stevenson; sanitary committee, J. W. Hughes, John Date, James Mattinson, A. Sigouin and J. C. Jacotel; arbitration committee, P. Carroll, A. Demers, G. Yon, G. Rosser and H. Baillie; auditing committee, J. Watson, A. Rousseau and Theo. Jacotel; legislation committee, F. Brunet, D. Gordon, J. Burns, T. Leclaire and W. Britton; apprenticeship committee, A. Demers, E. C. Mount, F. Jacotel, J. Bonhomme and J. Sadler.

THE NEW BUILDING BY-LAW.

The members of the Committee of the Province of Quebec Association of Architects to whom was referred the revision of the proposed city building by-law are finding their task an arduous one. They have held meetings regularly since last June, and now meet Tuesday and Friday in each week. Even though these meetings should be continued during the holidays, it is not probable that the work of the committee can be completed before the end of January. The members of the committee are: Messrs. A. C. Hutchison, A. T. Taylor, J. Nelson, A. Raza, W. E. Doran, Jos. Perrault, Jos. Venne, Victor Roy and J. Z. Resther.

MONTREAL STREET RAILWAY BUILDING COLLAPSE.

A lengthy investigation has taken place before a coroner's jury into the causes resulting in the accident to the Montreal Street Railway Company's new building, to which brief reference was made last month. A number of experts were called as witnesses, but as there was much diversity of opinion amongst them, we shall print only the conclusions of Mr. W. McLea Wallbank, B.A.Sc., M. C. Soc. C. E., and Mr. Lacroix, the City Building Inspector, who made an examination of the building by direction of the Attorney-General for the Province of Quebec, and whose opinions, as embodied in the following report, we should regard as being impartial.

R. D. McGIBBON, Esq., Q. C.,
Pro Attorney-General for Province of Quebec.

DEAR SIR,

Acting under your instructions I, in company with Mr. Lacroix, City Building Inspector, have carefully examined the Street Railway Company's new building on the corner of Craig St. and Place des Arms Hill, in order to ascertain the cause of the recent collapse.

The result of my examinations, calculations and tests goes to prove that the collapse in question has been caused by the failure of the 12in. brick wall supporting the two columns in the north-east portion of the building.

In order to ascertain the crushing strength of the bricks used we had the same tested at McGill College laboratory in our presence by Professor Bovey and Mr. C. B. Smith, the results of which have proved very conclusively that the strength of the brick depends almost wholly upon the manner in which the workmanship is performed in building same, viz, in using proper care to see that the bricks are properly wetted and thoroughly bedded in mortar.

We tested these bricks when bedded with cotton waste and cardboard and found that they failed as follows:—The first brick "A," bedded as above, failed at 395 lbs. to the square inch. This sample was bedded in Portland Cement also. "B" commenced cracking at 5 lbs., and failed at 428 lbs. "C" and "D" broke across the centre at 132 and 161 respectively. "E," cracked at 57 lbs. and failed at 393 lbs. "F" was bedded in Portland Cement on one side and loose sand on the top—commenced cracking at from 25 to 36 lbs., increased rapidly at 214 lbs., and failed at 625 lbs.

The above tests were with wet brick.

Dry Bricks: bedded with cotton waste and cardboard No. 1 failed at 139 lbs. No. 2 failed at 89 lbs. No. 3 failed at 143 lbs. per sq. inch.

PROPER BEDDING.

Not being satisfied that the bricks if properly bedded would fail with the small loads above quoted, we procured additional samples of brick from the building and had the same very carefully and evenly bedded in plaster of Paris, with the following results:

M, first crack at 1583 lbs., failed 2212 lbs.
N, first crack at 764 lbs., failed 885 lbs.
O, first crack at 417 lbs., failed 937 lbs.
P, first crack at 1385 lbs., failed 1559 lbs.
Q, first crack at 679 lbs., failed 1365 lbs.

R. This sample bedded on cardboard only, cracked at 85 lbs., fractured badly at 723 and failed at 946 lbs.

MORTAR.

A sample of the mortar is at present in the hands of Dr. Harrington, of McGill University, who will report on same about Thursday or Friday. I have also some samples of the mortar in my possession which I took from the building myself. I have made an estimate of the weight supported or concentrated on the 12in. wall at the foot of the column second from Craig Street and first from Place d'Armes Hill as follows: Area carried by top of column, 193.2. The weight of roof covering on roof composed of 1123 joists at 2 ft. centres an inch board over same would be neglecting bridging on blocks equivalent to 9 lbs. per sq. foot.

IRON.

One 15in. eye beam, 56 lbs., 21 ft. long					1176 lbs.
One 12in. "	32	"	9	"	288 "
Six 7in. "	14.7	"	10	"	882 "
One " "	17	"	3	"	51 "
					2271

This weight distributed over 193.2 of floor gives 11.75 lbs. per square foot.

TERRA COTTA.

I weighed a block of terra cotta which I found in the building and appeared to be a fair sample with cement on it and which I have still in my possession, and found same to weigh 20 lbs. The size of the block with cement was 4½x13. One of these blocks would give an area of 58 sq. inches, making the load about 50 lbs. to the sq. foot.

RECAPITULATION.

Wooden roof	9 lbs.
Iron	11.75 lbs.
Terra Cotta	50 lbs.
Total	70.75 lbs per sq.ft.

This load multiplied by 193.2 gives 13,669 lbs. approximately as the weight of the roof resting on top column.

Assuming that the fifth floor was similarly constructed, deducting the joists and roofing boards, the weight per sq. ft. of this floor would be 70.75, minus 9, equivalent to 61.75 lbs. per sq. ft.

193.2 multiplied by 61.75 gives 11930 lbs. as the load on the column supporting this floor in addition to the roof load.

Assuming that the fourth floor was similarly constructed to the fifth floor, there would be an additional 11930 lbs. for the wall supporting this column, to which should be added the weight of the columns themselves, which witnesses have stated to be 2400 lbs.

The total load therefore carried by the 12in. wall immediately under the column in question would be as follows:—

Weight of roof	13669	lbs.
5th floor	11930	"
4th floor	11930	"
Weight of columns	2400	"
Total	39929	" or 20 tons.

Size of bearing plate 12x18, equals 216 sq. inches.

Load per sq. inch was therefore 185 lbs.

The McGill University will send you a complete report of tests referred to and the bricks are still preserved and packed in a box at the College awaiting your instructions.

Yours faithfully,

(Signed) W. McLEA WALBANK,
Architect and Civil Engineer.
(Signed) P. LACROIX,
Building Inspector.

After having heard the testimony of the numerous witnesses, and listened to the coroner's charge thereupon, the jury returned the following verdict:—

"We, the undersigned jurymen, after having heard the proof, declare that Regis Panze, Adolph Leblanc and Joseph Marquis died in Montreal the 9th day of November, 1894, having been killed by the falling of a part of the building under construction for the Montreal Street Railway Company. We believe that the falling in was due to the fact that Ed. C. Hopkins, architect; Avila Gravel, engineer of the Dominion Bridge Company, and Joseph McLaughlin, foreman of the Dominion Bridge Company, failed to take reasonable precaution in the construction of the work, and that they cannot be excused for having neglected to fulfil this duty.

"We likewise believe it to be our duty to recommend to the municipal authorities that an amendment to the building laws be brought about, with a view to avoid such a catastrophe in the future."

Messrs. E. C. Hopkins, Avila Gravel and Joseph McLaughlin were thereupon arrested, but were subsequently released on giving bonds to appear when required to do so before the civil courts.

A SUCCESSFUL YOUNG CANADIAN.

QUEBEC, Dec. 1st, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—We translate from the French the following, which purports to be from "Le Canadian," of St. Paul, Minnesota, and which, while reflecting honorably on Canada and Quebec in particular, is also to the credit of the Quebec section of the Province of Quebec Association of Architects, under whose auspices the young man was admitted to the practice of the profession. The article reads as follows:

"Minnesota, one of the wealthiest States of the Great Republic, has decided on erecting a capitol to cost as much as a million and a half of dollars. 56 sets of plans have been sent in. Those designed by René Lemay are among the worthiest and most perfect, if we can credit what the St. Paul Despatch says on the subject. We have the plans before our eyes while writing this, and in truth the design is superb. We regret not being able to reproduce the longitudinal and cross sections which go to complete the design, which is by R. P. Lemay, assistant of M. M. Kretz & Co., Architects.

Mr. Lemay is the son of Pamphile Lemay, the well known Canadian poet. After long and serious studies under apprenticeship with Mr. J. F. Peachy, of Quebec, architect and member of the P. of Q. Association of Architects, he was by the Quebec Board of Examiners admitted to practice, when with his diploma he entered the office of M. M. Kretz & Co., who were not slow in discovering the talent of their young assistant, and who confided to him the execution of a plan which was to compete with those of the best architects of the United States. His efforts were crowned with success, and everything leads to the belief that the Commission will adopt the plans and specifications of our young Canadian friend."—COM.

COLLINGWOOD MEAT CURING ESTABLISHMENT.

It may not be generally known that one of the largest meat curing and packing industries in the Dominion is located in the town of Collingwood, but such is the case, and in this paper I will endeavor to convey to your readers, as briefly as possible, some idea of the building, its fittings, and the purposes for which it is intended.

The building, or rather buildings, stand near the shore of Georgian Bay, a little west of Collingwood harbor, the foundations going down to the limestone rock, which at this point, is only a few feet from the surface. The main building is 200 feet long by 80 feet wide, two stories high, of 12 feet each, with spacious attic, and a cellar seven feet clear, under the whole building. On the north side the building being longitudinally nearly east and west there is an addition 12×48 feet, three stories high, divided with brick walls into three smoke chambers, and a two ton hoist. The smoke chambers contain gridiron shelving, whereon to place bacon, ham or beef, that is to be subjected to the smoking process. Smoldering fires will be kept below, on a level with the cellar floor and the smoke will ascend to the top of chambers and escape through louvres in the roof. On the north-east angle, slightly detached, stand the engine house, boiler room, cold generating rooms and chimney shaft. These buildings cover a space about 32 feet by 50 feet with walls as high as the main building.

The chimney shaft is 88 feet high, including footings, and is seven feet square at the base, tapering to 3 feet 6 inches at the top, with a two foot by two foot flue at both top and bottom.

The whole of the outer walls, and two dividing partition walls, are of hard burned pale red bricks, and are two feet in thickness, with a hollow space of four inches between the inner and outer walls; the two thicknesses being tied together every fifth course with connecting links. The hollow space is well parged on both walls and every joint in the brickwork is well flushed up with properly prepared mortar.

As the roof is a particularly heavy one there are strengthening buttresses under the seats of principal rafters; the buttresses being solid brickwork from foundation up. The cellar story is of random coursed quarried stone, and is three feet thick, with air space in centre, which is well parged with cement mortar.

The footings are formed of immense blocks of granite four feet wide and one foot thick and of various lengths, laid down in the best Portland cement. Piers for the support of floors, machinery, tanks and roof, are scattered over the cellar and are formed of white oak resting on massive stone plinths. The cellar floor is a marvel of perfection, and is as smooth as a skating rink; it is composed of a layer of five inches of broken stones, a layer of three inches of slag, which is intended to act as a non-conductor, well tamped down, then a layer of grout or concrete, and finished off with a thick layer of Dykerhoff portland cement used in proportion of two of sand and one of cement—the whole being trowelled off until it is as smooth as glass.

The main floor is divided into twelve compartments, five of which are for storage, two for cooling, one for shipping, one for cutting up, another for killing and dressing, with a small room attached, 14×28, for preparing tripe. Another room is devoted to the manufacture and packing of lard. On this floor is a large room where the blood, offal and viscera are transformed into transputable fertilizers, and for this purpose an ingenious set of apparatus is set up and worked by steam. A mammoth press for expressing lard from the fatty substances is also in this room. The facilities in the killing room are such that 1000 hogs can be disposed of in twelve hours under pressure. Overhead tracks, of which there are some 3500 feet, convey the carcass to any required spot in the building where it is dealt with by the cleaner, cutter, &c. It is then placed in the cooling or chilling room until it is wanted for curing or for shipment.

The second floor contains six cold storage rooms, 15×65 feet each, all having five tiers of overhead tracks and capable of holding over 175 hogs each. All these cold storage rooms are kept at a temperature a little above freezing point by the ammonia system of cooling. Twenty-eight thousand feet of two-inch pipe is used in these cold storage rooms, and the whole system is worked by a 100 H. P. Wheelock engine, which, together with the cooling machine, is capable of making 35 tons of ice daily. The whole cooling system in the building is the work of the Wolfe Ice Machine Mfg. Co. Chicago, so also is the engine of 50 H. P. used for supplementary purposes, lighting, pumping, chopping meat, running presses, hoists, etc. The building is lighted throughout with an incandescent system put in by the Canadian General Electric Co. Shafting, pulleys, lard tanks and minor machines were furnished by the Goldie & McCulloch Co., of Galt, Ont., and the pumps, which are of the Blake pattern, are from the shops of the Northey Mfg. Co., Toronto. On the second floor is the singeing machine, where hogs intended for export have all the bristles singed off them in less than half a minute. On this floor is also a scalding vat, wherein the dead hogs are dumped, the water being made and kept hot by superheated steam. There is a large cutting and salting room, 50×50 feet, also on this floor and a sausage room 26×40 where sausages of every style are manufactured ready for export.

The full capacity of the building for killing, cooling and preparing for export is about 5,000 hogs and 3,500 hogs per week, and to manipulate this vast amount of material throughout its whole preparation will require an army of employees in and about the works, besides a large staff of buyers and agents. A thorough system of water-service, for fire and general purposes is provided on the spot, the water being taken from the lake.

In an article of this kind it is impossible to describe more than a few of the salient points connected with this enterprise, but I am persuaded the foregoing will give a fair average idea of the works.

The owners are Messrs. Thos. and J. Long, Frank and H. Telfer C. Stephens & Co., and G. Brown & Bro., to the latter of whom I am indebted for some of the figures given.

The Wilson Bros., of this town, designed and superintended the work, and the stone, brick and cement work, was executed under the supervision of Mr. Robert Burdett. At this writing the whole work is about completed, and killing will be commenced in a few days. A number of outside improvements are still going on, and will continue for some time yet. There has already been expended on these works about $80,000.

FRED. T. HODGSON
Collingwood, Ont.

LEGAL DECISIONS.

THE CITIZENS MILLING CO. VS. DEFOE.—A case of some interest to architects and builders, was decided by Mr. Justice Robertson and a jury about three weeks ago against the defendant. The merits of the case were about as follows: The defendant purchased a property on Adelaide street west which had been used as a billiard table manufactory. The building was of the ordinary type of such structures, built about twelve years ago. Dimensions about 114 feet long by 30 feet wide and four storeys high, including basement; good ordinary walls, centre beam running lengthways from end to end, 10"×12" in basement and ground floor, 12"×8" for the remainder, 12" round cedar posts in basement, six in number, dividing beam into seven bays of about sixteen feet each. The pillars on ground floor were some of iron and some of wood; iron circular 6" diameter, wooden ones 12" circular. All the columns were capped with solid pine corbels 10"×6", 4 feet long. The character of the remainder does not come into account. When the premises came into Mr. Defoe's hands in about 1891 he arranged it for a storage warehouse, putting in a power elevator, etc. The basement was used for heavy bulky articles, the ground floor for furniture, etc. The first and second floors were used by the Milling Co., mainly for the storage of flour in bags, and piled on the first floor seven bags high leaving narrow passages between the piles. Early in February of 1892 a portion of the floor carrying the heaviest load collapsed, the main beam broke and the greater portion of the contents of the various stories were precipitated into the cellar. On examination it was found that the main beam of the first floor where the greatest load was concentrated had become rotted, and the rot was traced to the action of steam from a steaming box which had been in use for years in the billiard factory previously there, but which presented no external indication of the weakness before the break. The jury decided that the safe load was exceeded and the verdict was against the defendant.

PROPOSED RESIDENCE FOR MR. HUGH GRAHAM, CORNER OF SHERBROOKE AND STANLEY STREETS, MONTREAL, QUE.—A. F. DUNLOP AND J. C. A. HERIOT, ARCHITECTS, MONTREAL.

PROPOSED HOUSE TO BE ERECTED AT KAMLOOPS, B. C., FOR MR. J. OGDEN GRAHAME.

FREE LIBRARY BUILDING, LONDON, ONT.—HERBERT MATTHEWS, ARCHITECT.

The free library building at London, Ont., is now being built under the supervision of Mr. Herbert Matthews. The materials used are as follows: Credit Valley stone facing for basement; Milton red pressed brick for superstructure; Ohsweken sand-stone—cut stone; Berea stone steps, &c.; windows glazed with French plate glass; roof covered with red slate. The interior will be fitted up in the most modern fashion, and it is expected that the library and museum, in connection with it, in their general arrangements and appointments will be a success.

PERSONAL.

Mr. J. W. Taylor, manager of the Toronto Radiator Mfg. Co., is passing through a severe illness.

We are pleased to learn that Mr. Eustace G. Bird, of Barrie, formerly of Toronto, has received the degree of A. R. I. B. A., having passed the examinations last March of the Royal Institute in London, and being elected an Associate last month.

A partnership has been formed, between Mr. Eden Smith, of Toronto, and Mr. Eustace G. Bird, of Barrie, as architects, with offices at Toronto and Barrie. Mr. Bird, has lately returned from England, where he was with the well known architect, Mr. Colcutt, of London. Mr. Smith is well and favorably known.

Messrs. Gurd and Burke, architect, Toronto, has admitted to partnership Mr. J. C. B. Horwood. Mr. Horwood served the earlier years of his studentship in the office of Messrs. Langley & Burke, Toronto. He has since had the opportunity of gaining valuable experience in the offices of leading architects in New York city, and has recently spent some time in England and on the continent. Mr. Horwood will be a decided acquisition to the ranks of the profession in Toronto, and the partnership into which he has entered with Mr. Burke should prove to be mutually advantageous.

THE PRACTICE AND PROVINCE OF THE ARCHITECT.*

I VENTURE to draw your attention briefly to a few considerations affecting the practice and province of the architect. Foremost amongst the essential elements of architectural practice I would place what I may describe as an artistic sense—the faculty of recognizing and enjoying the beautiful in all things. And, more than this, an open vision to see, and wisdom to understand, the great underlying principles out of which all true beauty, whether in nature or art, grows. The direction of the student's work will depend much upon his tastes; but a study of the best examples in Classic, Gothic, and Renaissance architecture is certainly desirable. The aim of such studies should be fundamental, not with the object of slavishly copying, but of learning the principles upon which the builders wrought; and thus it will often be found that some of the principles are the same in widely differing styles. We are often twitted in this country with having no national style, but—as the Americans say of our weather—possessing "samples only." I take it we must admit the criticism. But may not this fact be due in some measure to the oftimes wrong direction of our studies? It is scarcely a generation back since it was a common practice to regard ancient Classic examples as objects to be copied bodily—at least, as to elevation. The interior purpose of the new building might even be wholly different from those of the original, but convenience of plan had to succumb to an imposing façade. The Gothic revival only in a measure mended matters, for a time, for a somewhat slavish copying of detail, apart from a proper understanding of principles, became the fashion. This period, through which we have now happily passed, has doubtless had its uses, nor can we yet afford to set aside a careful study of Ancient and Mediæval art. It were indeed far better to copy bodily a good design than to invent a bad new one. But the evil is that buildings, like plants, are often indigenous to the soil, and ill-adapted for transplanting to another clime. Though the maxim is not a new one, we have perhaps not yet come fully to understand how a national style can scarcely exist, at least can only be good, as it grows out of, and fitly expresses national habits and characteristics. But when we speak of the "practice" of the architect, the word itself suggests that something more than the possession and efficient training of the artistic sense goes to the making of an architect. He must also undoubtedly possess not a little practical knowledge of several sciences. To the vexed question, whether an architect should be an artist or a theoretical mechanic, I would reply: In a measure he must be both, and a man of business too. An artist may be a thoroughly unpractical man, no man of business, and yet be a good artist; an architect cannot. On the other hand, neither has the mere mechanic, or man of business, with perhaps little art sense, and no art training, any claim to call himself an architect. He may be well versed in the science of building, and able, most efficiently, to conduct the business of his client, but he cannot be a true architect unless he be a true artist. Lacking this, though his buildings be very ornamental, the ornamentation will probably be vicious, and though his work secure many admirers, it will inevitably be devoid of the elements of true beauty, and transgress at every point canons of good taste. Time will only permit of a brief mention of two features of the times which present special hindrances to architectural practice. The mania for cheapness thwarts us at every point, often curtailing expenditure below reasonable limits, and tempting to the improper use of materials made to imitate the functions of more costly substances. The multiplication of specialists' manufactures by way of fittings and decorative features, though it sometimes saves us trouble, tends to sameness of treatment and loss of originality, and often unhappily to the fostering of a vitiated taste for showiness and a wholesale destruction of true art. The qualifications for the practice of architecture are wide in their range, and certainly such as to make large demands upon the powers of most men. I think, however, you will be ready to admit that they are not unreasonable. But does not every consideration of the subject point again to the absolute need for a careful education and training for every architect?

Let us now turn from the qualifications for the practice of architecture and inquire what are its limitations. What is the province of an architect? One thing must be evident. Unless he become a specialist the variety of the buildings which an architect may be called upon to design will of itself present a wide scope for the exercise of his talents. He may be to-day designing a church, and to-morrow a dwelling house, school or factory. He need not, it is true, have a previous knowlege of all the technical requirements for which such buildings, for instance, as factories are needed; but he must be able readily to grasp these requirements, to invent methods for overcoming difficulties, to guide and advise clients who often scarcely know their own needs, and to throw all into forms of beauty framed out of suitable and enduring materials. Such duties are not light, and surely a man with any amount of practice might find in their faithful exercise ample scope for time and genius. But what are the facts of the case, gentlemen? A study of local Directories would lead us to suppose that many architects must indeed be men of Herculean powers. In fact, architecture seems to have been tacked on as a light and pleasant pastime relieving the more serious occupations of house agency or upholstery. In these days of keen competition it becomes a matter for quite serious discussion what occupations, if any, beyond his evident sphere an architect may fitly engage in. It would often doubtless be to his pecuniary advantage to undertake house and estate agency. It must, however, always be to the detriment of his art; if such a combination can be justified at all, it should at least be by way of recognized partnership, the partner who has been trained as an architect having freedom to give his undivided attention to architectural work. It has always appeared to me perfectly legitimate, and sometimes advantageous, for an architect to take out his own quantities. He must know best his own intentions, and if he has a proper knowledge of the science, should be best able to make the quantities a true expression of those intentions. An architect in large practice will, however, not often have time for this. When the work is done by a surveyor, he should be working in full concert with the architect; and whether the quantities form a part of the contract or not, it would be better if they were always recognised and paid for by the employer.

Land surveying, and the laying out and development of estates, is another large branch of work in which architects frequently engage. As regards the former it is certainly admissible for an architect to measure and level the sites for his own works, and he should at least be able to do this. In respect of the latter, it would doubtless be much to the advantage of the estates if an architect had at least some share in their planning. In this, as in other matters, very much must depend upon the time at his disposal. I cannot see that there is necessarily in the work itself anything inappropriate or injurious to the proper exercise of architectural art. Surveying for delapidations is another branch of work which, at least in the provinces, is always regarded as coming within an architect's practice. It is certainly one which his general experience specially fits him to perform judiciously. The question whether architects should advertise opens an oft-debated point. Much depends upon the manner of advertising. It cannot reasonably be denied to an architect to use some legitimate means of making himself known. But should not his works be his best advertisement, and why should he not place his name upon them in some modest spot, as an artist or sculptor does? There is something very different in this from the ordinary trade advertisement. For myself, I much doubt whether advertising in the ordinary trade sense is of any use to an architect; but whether it be so or not, it is utterly repugnant to good taste. The following is an actual specimen of this kind of advertising, which fortunately has not yet become common amongst architects:—"Designs for chapels and schools. Pretty, inexpensive; free from damp and echo. Upwards of eighty have been erected during the past eight years, and the demand is still increasing." And then follow paragraphs headed:—"Architectural Beauty, Echo, Damp, Ventilation, Extras and Disputes," &c., in all of which points the author claims exceptional success. The circular closes with an offer to forward photographs or lithographic views of chapels in various styles at a charge of 6d. each below 400 sittings, and 9d. each above. Comment is superfluous! It is not always easy to stand against the fashions of such an advertising age in which literary men and even ecclesiastics are sometimes led into the stream. But to my mind all eulogistic comments upon the creation of one's own brain are out of place, and must so tend to lower one's higher sensibilities as to become reflectively injurious to our art. It behoves us, therefore, as a Society, very strenuously to set our face against such practices. Against the acceptance by architects of commissions from manufacturers and others, it is scarcely possible to utter words too strong. Architects are doubtless often put to much trouble in selection, and the unwillingness of clients to fairly remunerate for such work is strong inducement to them to seek their commission elsewhere. But the argument is specious and insufficient to uphold what can only be characterised as deception. My aim throughout has been to demand a high standard in the exercise of our art. With class distinctions of trade and profession I have little sympathy. A calling is honourable as it is exercised honorably. Every man who does his best, whether in art or craft, is worthy of respect. But assuredly all callings do not require the same degree of ability. And without any invidious comparison it may safely be averred that the practice of architecture ranks high amongst the professions, as one making large demands upon talent, study, and close application. It is on these grounds that I would urge the limitation of architectural practice as much as possible to what is certainly the main province of the architect, namely the designing and superintending the erection of buildings.

* From the inaugural address of the President of the Society of Architects.

The manufacturing business of the Chanteloup Estate, Montreal, has been purchased by the Chanteloup Mfg. Co. Ltd. The business will be conducted under the management of Mr. Wm Robinson.

Messrs. B. L. Nowell & Co., of Montreal, have been appointed Canadian agents for the Royal Cement Plaster Co., of St. Louis. This cement plaster is mixed with good sharp sand in the proportion of 100 lbs. of the former to eight ordinary water buckets of the latter, and thoroughly tempered to a good stiff mortar.

To make canvas waterproof, it is usually first wetted, then coated with two coats of boiled oil, using very little turps and driers. When thoroughly dry two coats of paint of the desired color, or better still, three coats are put on thin.

CONCRETE CONSTRUCTION—ITS PRACTICAL APPLICATION.*

BY ERNEST L. RANSOME.

THE practical application of concrete may be conveniently divided into four divisions, viz.: 1st. False work. 2d. Materials. 3d. Tools. 4th. Labor.

The second division can be usefully divided into four sections, viz.: A. Cement. B. Aggregates. C. Iron. D. Water.

DIVISION 1.—*False Work.*—Concrete, in respect to false work, is unfortunate in comparison with other masonry because it not only needs more expensive centering whenever centering is necessary, but it also usually requires cribbing, whereas other masonry does not. This characteristic entirely prohibits its use in many cases where in all other respects it would be desirable, and it is therefore an obstacle to the more extended use of this valuable construction that should be minimized as much as possible. Of late years I have met with considerable success by adopting systems of standard centering and cribbing, which, while not of universal application, are of great use, permitting, as they have done, of the construction of floors and buildings that otherwise could not have been attained; but as this is of interest to the contractor rather than to the architect, I will not enter into a detail description thereof.

Great difficulties have often arisen from the swelling of the sheeting of the centering or cribbing, caused by the wood absorbing the moisture of the newly placed concrete. From this cause many arches have been lifted and broken, floors cracked and walls thrown out of line. By using sheeting boards of a moderate width, say six to eight inches, and beveling one edge slightly, the boards may be put close together and when expansion occurs the only effect will be to slightly crush the sharp outer edge of the bevel, without lifting or disturbing the concrete abutting or resting upon it, the widest side of such boards being of course placed facing the concrete.

This is a very inexpensive, simple and unfailing remedy that from its conception I have used in all cases, and since its use I have never had any trouble from swelling of the timber. Some such device as this is especially necessary in dry climates, also in light constructions, such as floors of but an inch or two in thickness, or hollow walls.

For standard centering or cribs, if of wood, it is advisable to make them of planed lumber. The surface of the wood should be thoroughly coated with common thick kerosene oil before it is used for the first time, and before each subsequent use it should be brushed over afresh with the oil, or else with a paste made of castile soap and water. Fish oil is objectionable, as it is apt to injure the surface of the concrete, and linseed oil is generally too gummy for this purpose.

It may be accepted as a general rule that false work of light sheeting, well braced, is more economical than heavier planks with braces farther apart. I am aware that this is not the usual practice.

The ornamental effects can be much more cheaply produced by recessed than by projected work.

Materials.—Under this head cement, by reason of its greater cost and active qualities, stands out preeminent. I will limit my remarks under this subdivision to Portland cement, with the exception of the following observation, viz:

That where rapidity of construction is not a great object, and aggregates are unusually cheap, by the use of common lime, with or without some of the cheap native cements, properly handled, work of good quality and of astonishing cheapness can be made—one part of lime to forty parts of aggregates not being considered too little in some cases.

Portland cement, a giant from its birth, is striding rapidly along in the way of improvements in quality and price, so that formulas of tests that were thought severe a few years ago would not be considered sufficiently exacting at the present time to ensure as first-class the cement that would successfully pass them.

The current technical literature teems with methods of testing, so that we can hardly go astray in the selection of a good cement. The three principal requisites for a first class cement are as follows:

1st. That it sets or hardens without undue expansion or contraction.
2d. That it be sufficiently finely ground.
3d. That its tensile strength be high.

The usual methods of ascertaining these points are:

1st. The cake test. This test is so well known that a description of it here is unnecessary. When time is an object, by the use of hot water the test may be hastened. Under expert supervision the "boiling test" is by many considered superior to the cake test, but the difficulties in the way of carrying it out and some uncertainties in the results that yet linger about this new test prevent me from advocating its substitution for the older test.

2d. The test for fineness. Ninety per cent. of the cement should pass through a hundred-mes screen having 10,000 holes to the inch. It would be better to use a yet finer screen for testing, but for the difficulty of obtaining finer screens. The practice of using coarser screens is to be condemned because they pass much that is inert. The screenings should feel soft and silky to the touch. The residue on the screen should be hard, black, angular grains. The economic importance of fine grinding has seldom been exaggerated. It is usually unduly disregarded, yet it has been established beyond reasonable doubt by repeated experiments that the sand-like grains of the cement are practically inert and useless. Still, unlike the first qualifications, this is an economic question, and the ill effects of coarse grinding, if not apparent in the first test, can be overcome by making due allowance for the coarse portion in proportioning the cement to the aggregate and then but little harm will follow the use of coarse ground cement in ordinary work.

3d. Tensile strength. This test is usually and best made by the aid of the ordinary testing machine. Several first-class cements will now develop tensile strength of 600 or 700 pounds per square inch in seven days, and while this may be too high a standard to insist upon, yet the cement that will not furnish a strength of 450 pounds in seven days ought not, in my judgment, to be graded as first-class, unless it is exceptionally fine ground.

With regard to the aggregates not so much has been published.

Sufficient interest is not usually taken in these inert materials, which, nevertheless, have a powerful influence upon the character of the concrete, so much so that a good aggregate with a poor cement will sometimes give better results than a good cement with a poor aggregate.

A first-class aggregate should be made of a hard, tough rock, free from clay or dirt and having a rough surface and sharp angles when broken; it should be so graded from the finest grains to the largest pieces admissible in the work it is for, as to give, while retaining the largest proportion of large sized pieces, the smallest proportion of voids.

If the aggregate is all of one material, the desired aggregation can be determined by weighing a given measure. That proportion which, while retaining the maximum amount of large pieces, weighs the most, is the best. If, on the other hand, the aggregate is composed of different materials, then that proportion which in a given measure and under the same limitations as just given, will permit of the introduction into the filled measure of the least quantity of water is the best.

In making such tests the larger the measure the better; a round measure is better than a square box, and it should not contain less than two cubic feet. The material also ought to be shaken down into the measure. It is desirable, when time will permit, to make these tests with a mixture of one of cement to three of sand, but ordinarily with cements of equal fineness the relative strength of different brands will remain about the same as under the test with neat cement.

For fireproof work care should also be taken to avoid such aggregates as contain feldspar, and where the possibility of the concrete being subjected to a long continued red heat is sufficiently probable as to be worthy of precautions being taken to meet its effects, limestone also should be rejected from the aggregate.

To those who have studied the matter practically, it is evident that in the large majority of cases the prejudice against the use of the dust and fine particles created in crushing brick or stone is unfounded, and the practice of prohibiting these and substituting therefor ordinary sand is strongly to be condemned. Lieut. Innes found that both limestone dust and ground, burnt clay, gave stronger results than the purest sands, and tests and works carried out under my supervision thoroughly corroborate this.

The largest stone does not necessarily make the best aggregate.—For instance, finely crushed granite is for some purposes inferior to finely crushed limestone, although as a rule the granite is the harder of the two. One reason for this is not hard to seek: Owing to the brittle quality of granite, in crushing it is not only broken into small pieces, but many of these pieces are so bruised and contused that upon a little pressure being exerted upon them, such for instance as can be applied by the finger or thumb, they will crumble. With limestone and many other softer rocks, by reason of their greater toughness and elasticity, this is not the case.

Again, some stones, as quartz and the like, have surfaces of such smoothness that the adhesion of the cement thereto is not so good as that between cement and other stone, such as basaltic lava, sandstone and the like, which, when fractured, present a rough surface. Such stones as these latter usually make first-class aggregate. Broken stone, as a general thing, is a better aggregate than gravel. Sometimes a mixture of the two is preferable to either alone. Usually the use of one or the other has to be determined by the economic side of the question and the local supply. When from such causes gravel is selected, its quality can be greatly improved, at small cost, by running it through a crusher that will break the larger pieces as they pass.

The common practice of limiting the maximum size pieces so that they will pass through a three-inch ring is, I think, open to question. In massive work, stones much larger may advantageously be used, not, however, if the late fashionable practice of "dry concrete" be adhered to.

The experiments carried out by Mr. Elliott C. Clark tend to show that the presence of a small amount of clay in the concrete is no detriment to the strength of concrete, even with clay, as much as ten per cent. of the aggregates and cement combined.

In corroboration of this I would instance the Niagara gravel, which, whilst it contains a marked quantity of clay, yet makes most excellent concrete.

Having determined the aggregate, the next important question is, what is the proper proportion of cement to use for any given work?

When first-class materials, in round figures and within the limits of proportions between the cement and the aggregates of from 1 to 4, to 1 to 15, the crushing strength of concrete, when skillfully made, at a month old may be taken as follows in tons per square foot: Multiply the *constant* number 700 by the number representing the proportion of cement used, and divide it by the relative number representing the amount of aggregate used; for instance, a concrete composed of 1 part of cement to 14 parts of aggregates should, when properly seasoned, have a crushing strength of $\frac{700 \times 1}{14} = 50$ tons; when three months old the strength will have increased some twenty-five per cent., and when twelve months old it will have increased some fifty per cent.

Under this rule a concrete composed of 1 of cement to 14 of aggregate would be about on a par with good brick work when a month old, and be about fifty per cent. stronger when twelve months old. This rule reduces the strength of the concrete too much as the proportion of aggregate is increased, but it is reasonably correct and quite safe to act upon.

SECTION C.—*Iron.*—The tensile strength of concrete is comparatively little, and by reason of the gradual though slight shrinkage that takes place in all concrete structures that age in dry situations, should not be relied upon in any important work.

For giving tensile strength to concrete, all modern workers of note now use iron in some form or other.

Angular iron bars, cold-twisted, commend themselves in many ways, and on this continent they have been more largely used than any other form in concrete iron construction.

The advantages of this cold twisting are many; they may be summed up as follows:

1st. The tensile strength of iron is largely increased, viz., from 20 to 50 per cent., dependent upon quality of iron used.

2d. Its elongation under strain is considerably lessened, a very important advantage in concrete-iron construction.

3d. It forms a *continuous* key with the concrete, both longitudinally and also athwart the bar. The effect of the twist is to *grip* the concrete in every direction, and in fireproof flooring and other work where light construction is desired, the importance of this universal key is very great, for it counteracts the tendency which the bar otherwise would have to split the concrete along the line of tension.

4th. The cost of twisting is nominal, and the royalty for its use not prohibitory.

In placing these bars care should be exercised in putting them in position where they will best exert their strength. They should be straight and laid directly in the line of strain. Any deviation from this rule should be such that the tendency to straighten, which invariably occurs upon the application of the strain, will do little or no damage, such a deviation, for instance, as laying the bar of a floor beam with a slight sag in the centre. In such a case when the strain takes place the tendency to straighten would have the effect of thrusting the centre of the bar upward against the downward thrust of the load, and it would be harmless. If, on the other hand, the bar was laid crowning in the centre, upon the floor being loaded, the tendency of the bar to straighten would be in the same direction as that of the downward thrust of the floor load, and the consequences would be detrimental, if not fatal, to the integrity of the structure.

Concrete is an excellent conservator of iron. Von Emperger states that he knows of a case where iron rods were found perfectly rust free after having been imbedded in concrete below the water level for forty years. (T. A. V. C. E., Vol. XXXI., p. 447.)

W. G. Triest, Jr., states that a wrench that had been buried in concrete twenty-two years had kept its black metallic surface. (T. A. V. C. E., Vol. XXXI., p. 467.)

Referring to some concrete foundations that I built about ten years ago, the president of Star & Co. writes, as follows, under date of December 30, 1893: "Though this foundation is on tide land and submerged in salt water more than half way up, there is no rusting or deterioration to the iron. We had occasion to cut through one of the arches and found the iron as stated." A long time ago I imbedded a dozen pieces of hoop iron in as many blocks of concrete, leaving one end of each piece of iron projecting from the surface. After years of exposure to sea air, all the exposed iron had rusted away, or so nearly as to leave but a few soft, jagged needles of rust that were readily removed by the hand. In all cases upon cutting into the blocks I found the iron almost as good as new, and from one to two inches from the surface it was invariably so.

SECTION D.—*Water.*—The water for mixing should be clear, and by preference soft. If it cannot be obtained of ordinary purity, then due allowance should be made for the impurities by an additional quantity of cement.

Sufficient water should be used to bring the mass when thoroughly mixed into a stiff, sticky, tenacious, viscous condition. An error as to the amount of water that should be used in concrete some years ago crept into the professional practice both of engineers and architects, and with surprising rapidity permeated and revolutionized it. I allude to the erroneous theory that only sufficient water should be used to slightly moisten the mass, and hardly enough to render it cohesive in its unconnected state.

An error seldom takes the hold this did upon a skilled body of men without some apparent justification. The only justification that I have been able to find after considerable research is the fact that, in making briquettes for testing purposes, the use of a minimum quantity of water gives the best results. From this one little isolated fact the generalization was made that, to produce the best results, concrete should be mixed in like manner. The fatal flaw in this deduction lies here, viz.: that a mixture of cement, or of cement and sand, with water, differs radically in conditions when to either of these gravel is added, and differs yet more when broken stone is used.

If cement, or cement and sand, is mixed with a large proportion of water, it cannot be compacted by blows or such pressure as can usually be brought to bear, for the mixture would flow from under the tamper. In the latter case, however, where gravel or broken stone is used, with a larger proportion of water, the concrete can be compacted more intimately and closely than with the minimum quantity, and under all ordinary conditions makes a much better concrete. The only exception to this is where smooth, rounded pebbles only are used with the mortar of the concrete, but this exception does not apply to ordinary gravel and never applies where broken rock is an ingredient. I allude to this at some length, because the error, although on the wane, is still widespread.

DIVISION 3.—*Tools.*—There is great advantage and economy in mill mixing. Mills can now be obtained at a reasonable figure and should always be used on large works. By their use the cement is more fully utilized, the cost of labor lessened and the work is more uniform and satisfactory in character.

An objection is often made to mill-mixed concrete, viz., that the concrete is injured by overmixing. What is "overmixing?" A very rare *distemper*, this. I have never once met with it, although I have been actively engaged in concrete construction for thirty-five years. It is never epidemic or fatal, but like vaccination, if present, it would prevent worse and more fatal ailments.

Mr. Spencer Newberry found that a mixture of one of cement to three of sand, which when worked for one minute with a trowel developed a tensile strength of 87 pounds in seven days, developed a strength of 240 pounds in same period after being worked with the trowel for five minutes; a remarkable result, surely, and well worthy of consideration.

Contrary to the almost universal opinion, Portland cement is improved by a delay between mixing and placing. I have experimented with several brands of Portland cement and find that they were invariably improved in tensile strength by a delay of from one to four hours between mixing and placing.

In placing concrete it is preferable to have it of one uniform consistency throughout the mass. In cases, however, where it is required that the face of the work should be of a finer grade, both grades should be carried on simultaneously, the face grade being placed up against the sheeting or mold a little in advance of the backing by means of a trowel or other convenient tool. In more careful work thin strips of iron about six inches wide and of any lengths convenient, may be set up on edge in the concrete parallel to and at any desirable distance from the face of the mold. The face concrete should then be inserted between the mold face and the iron while the backing is placed at the other side thereof. As each layer is put in the iron is drawn up a few inches, so that when the concrete is tamped the effect of the tamping is conveyed below the lower edge of the iron, and causes the two grades of concrete to become thoroughly united and monolithic.

The material should in ordinary cases be placed in thin layers, seldom greatly exceeding in depth the length of the largest aggregates used, and these layers should follow one after another sufficiently quickly so that one layer does not become stiff or partially set before the next is upon it.

Flat tampers should not be used for massive work except in the first and last layers of the day's work; thin or edge tampers should be employed. Wherever practicable the concrete should be compacted by rolling, in preference to tamping. It is cheaper and much more effective. I am not aware of its being done outside of my own practice, but it is certainly deserving of almost universal use. On large work steam rollers would be excellent.

It may be accepted as an axiom that concrete cannot be too thoroughly compacted, provided the action is not violent enough to bruise or crush the aggregate.

In massive or deep work, as it proceeds through the day, often the working surface becomes richer in mortar, when, and as often as this occurs, the mixture should be changed by adding thereto more of the larger aggregates free from fine dust, sand or gravel, until this fault is remedied. If on the contrary at any time the surface becomes open for lack of mortar, it should be immediately remedied by putting into the mixture a lesser quantity of the larger aggregates and not substituting anything in their place.

In a similar way the amount of water used in the mixings should be regulated, changing to more or less as the working surface appears too stiff or too watery. It should be firm under the tamper or roller and yet the mortar should be viscous and unctuous to the touch.

The quantity required to produce this condition varies greatly, dependent upon the character of the aggregates, whether but slightly or very porous, and upon the age and character of the cement and weather.

Great care should be observed in joining the work of one day to that of the next. The last layer should be thoroughly compacted and left with a slight excess of mortar. It should be finished with a level surface, which, at proper time, as soon as sufficiently stiff, should be patted or stippled with a steel float so as to produce a surface studded thickly with little conical knobs. This surface should be kept wet throughout the night, and in the morning immediately before the application of the first layer of fresh concrete it should be covered with a wash consisting of a mixture of equal measures of Portland cement and air-slacked lime, mixed with water to the consistency of thick cream. This covering should be put on in excess and brushed thoroughly back and forth upon the surface so as to insure a close contact therewith, the excess being swept along just ahead of the fresh concrete until all the surface has been covered, when it should be removed.

When in place the concrete should be kept moist for as long a period of time as possible. When one bears in mind that the chemical action which causes the cement to harden can only take place in the presence of moisture, the importance of keeping the work wet is at once apparent.

In all concrete construction excepting subway and other works where the concrete remains permanently moist, provision should be made for the slow but certain shrinkage that takes place in the concrete as it becomes thoroughly dehydrated. The vertical shrinkage will take care of itself, as the weight of the building is in harmony with its movement. The horizontal shrinkage, however, is resisted by the inertia of the structure and the friction of its foundation. There are several ways to direct such shrinkage; that which I have found most feasible is to partially divide the wall at certain intervals, preferably over the windows where there are several in line, and to insert across the division a weathering strip of copper or lead.

Where the appearance of a straight division line on the face of the building would be objectionable, for instance a wall blocked off into ashlar face, I build this division straight and cause it to coincide with the line of the V recesses of the ashlar, marking in every other course, and I block out in the intermediate courses recesses opposite to the division line, and subsequently fill these recesses with concrete ashlars made and seasoned beforehand. By adopting the pattern of alternate long and short ashlars in every other course with long ashlars only in the immediate course meeting at the centre line of the short ashlars above and below them, there separate concrete ashlars may be made small, and the additional cost of their manufacture will be but trifling.

Apart from the question of appearance, some such division of the surface of a concrete wall is advisable for a two-fold reason: some defining line is needed at the juncture of each day's work at least, and by dividing up the surface by deep recesses into small sections, surface cracking is largely avoided.

In reference to this shrinkage of concrete, lest I should have unnecessarily alarmed you, I will state that in a building, the walls of which were 170 feet long and divided thus, it was nearly two years before any apparent shrinkage took place, and now it can hardly be observed by a minute examination of the division joints. No outsider, even though a careful observer, would be likely to perceive any effects of this slight shrinkage when thus controlled.

In situations where it is not possible to make shrinkage joints by a liberal use of twisted iron, shrinkage cracks can often be prevented.

THE RESISTANCE OF PORTLAND CEMENT CONCRETE TO THE DESTROYING ACTION OF FIRE.

By a misunderstanding, due to a windy interference (Mr. Stone tells me one of my letters was blown out of his office window), I find I am expected to speak on the protection concrete affords iron in case of fire.

There seems to be not so much data on this subject as one would desire. What little there is, however, seems to be in favor of concrete as a fire resistant.

It is generally understood that the artificial stone made with Portland cement concrete withstood the Chicago fire well. Some years ago the blacksmith's shop at the Benicia Arsenal, California, was burned out, leaving the outer walls standing. This was a brick building with granite door sills, free stone belt courses, with window caps and cornice of Portland cement concrete. I examined the ruins carefully. The granite was spoiled badly and broken into several pieces; the freestone was badly broken and injured; the brickwork was burnt out in the joints in many places, rendering the walls unsuitable, many of the bricks also being spoiled, whilst the concrete window heads, which had probably to bear the brunt of the fire on the outside, were but little injured; the surfaces had softened a little and were badly discolored, but they remained whole and strong.

Concrete bricks made of well burnt clinker and lime by a process which converts the lime into a silicate of lime, thereby making it resemble a Portland cement in character, withstand the action of a hot fire and the subsequent sudden cooling by water better than any burnt brick, either common pressed or firebrick, that I could obtain in San Francisco, and I presume the same relative result would be obtained from most of the bricks of the several States.

I have repeatedly made the tests so severe that every burnt brick in the dozen or so tested at a time broke into two or more pieces, whilst under the same test the concrete bricks, beyond discoloring slightly, showed no change.

THE THERMIC EXPANSION OF PORTLAND CEMENT.

Bonnican Bonnicean is quoted as giving the expansion of Portland cement at 0.00000143 for 1 celsius, and iron is given at 0.00000125, which is practically the same.

Hyatt corroborates this in some careful experiments he made with loaded floors submitted to fire, in which the concrete-iron construction bore a red heat for several hours without injury.

Throughout Europe I believe hollow tile construction is almost unknown. Concrete floors are commonly used in fireproof buildings. The result of tests undertaken in Germany under Government supervision to ascertain the relative value of the ordinary building material, including brick work, places concrete at the head of the list as the best fine resistant.

If due regard is paid to the aggregate used, so that feldspar is avoided, and limestone also, where the structure is liable to prolonged hot fire, I think it will be found that Portland cement concrete is an excellent fire resistant.

PUBLICATIONS.

A new and artistic catalogue has just been issued by I. P. Frink, manufacturer of reflectors, New York, a copy of which will be sent on application to any of our readers.

"Industrial Agreements and Conciliation" are the tropics treated by the Hon. C. C. Kingston, Premier of South Australia, in the December of the Review of Reviews; the magazine is publishing a series of articles by leading Australian statesmen on questions of immediate interest to American readers.

The Pease Furnace Co., Toronto, have recently published an interesting catalogue, in which is fully described their heating system and the method of securing best results therefrom. Illustrations of public and private buildings heated by their system, and testimonials from persons having it in use, are likewise given.

Of the second edition of the Canadian Contractor's Hand-Book, Mr. Chas. Baillairgé, Architect and City Engineer, Quebec, expresses the following opinion: "A valuable work of most useful and suggestive memoranda and tables, and worthy of an analytical index—the Table of Contents "as given affording a very incomplete idea of the information conveyed."

* A paper read at the Twenty-eight Annual Convention of the American Institute of Architects, held at New York October, 15, 16 and 17, 1894.

PROPOSED ORGANIZATION OF LEAGUE FOR THE ADORNMENT OF THE CITY OF CHICAGO.

CONSTITUTION.

ARTICLE I.—The name of this organization shall be the "Chicago Municipal Improvement League."

ARTICLE II.—The purpose of this League shall be to secure for our city such an arrangement, design and adornment of our public buildings and grounds, streets, boulevards and other public works as shall most contribute to the convenience and enjoyment of the public; stimulate an appreciation of art and give to the city a fixed expression of its greatness.

ARTICLE III.—This League shall be a union of committees, of three each, elected or appointed by such organizations interested in the above objects, as shall respond to the invitation of this League. The following organizations are represented in the formation of this League and are hereby invited to continue their co-operation by making their committees standing committees for this purpose, viz: The Illinois Chapter of the American Institute of Architects, Western Society of Engineers, Chicago Society of Artists, Chicago Real Estate Board, Chicago Builders' and Traders' Exchange and the Civic Federation of Chicago. Other organizations may be invited to co-operate with this League by a two-thirds vote of the whole number of members.

ARTICLE IV.—Each committee of three, appointed by a co-operating organization, shall be a standing committee of this League on the subjects that come within the scope of the organization which it represents. Each committee will serve as a means of communication between this League and the organization which it represents. No action of this League is to be binding in any way upon the co-operating organizations, but is to be advisory only.

Each committee shall have a chairman elected by itself or the organization appointing it.

ARTICLE V.—The chairmen of the several standing committees shall constitute the Board of Directors.

ARTICLE VI.—The following officers shall be elected by the Board of Directors from their own number. A president, a vice-president, a secretary and a treasurer.

ARTICLE VII.—All officers shall be elected immediately after the annual meeting by a majority ballot vote of the directors present. Officers shall be elected for a term of one year and until their successors have qualified.

ARTICLE VIII.—It shall be the duty of the Board of Directors to have general charge of the work of the League; referring special investigations to the appropriate standing committees. All expenditures of money shall be under the control of the Board of Directors who shall devise and carry out means for raising the necessary funds.

ARTICLE IX.—The annual meeting shall be held on the second Tuesday of November, at which time the several committees shall announce their selection of members for the Board of Directors.

Other meetings may be held on the call of the President or the Board of Directors. The President shall call a meeting on the request of any five members. Co-operating organizations are requested to appoint their committees during the month of October, so that the change of membership may take place at the annual meeting, at which time reports shall be presented by all these committees. These reports shall be sent to all co-operating organizations.

ARTICLE X.—A majority of the League or any committee shall constitute a quorum.

ARTICLE XI.—This constitution may be amended at an annual meeting without previous notice, or at a special meeting upon notice of proposed amendments at least one week in advance, by a vote of two-thirds of the total number of members.

ARTICLE XII.—The officers elected at the organization of the League shall hold office until November, 1895.

A rule to determine the ready quantity of paint required to cover any structure, says the Plumber and Decorator, is as follows: Divide the number of square feet of surface by 200, the quotients will be the number of gallons of liquid paint required for two coats. Or, divide the area in square feet by 18, and the result is the number of pounds of pure white lead required to give three coats, where this pigment is permissible.

WARNING

OUR subscribers and advertisers are hereby notified that persons authorized to collect accounts for this Journal are furnished with a special receipt form, headed "Official Receipt," and this is the only form of receipt which will in future be recognized in the case of accounts paid to collectors.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 1. JANUARY, 1895 {PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

VOLUME VIII.

To mark the commencement of a new year and the entry of the CANADIAN ARCHITECT AND BUILDER on the eighth year of publication, the present number is presented in holiday attire, and exhibiting special features in the way of illustrations and letterpress which it is hoped will be regarded with favor. An effort has been made to compile a statistical review of building operations in Canada for the year which has just closed, and to indicate as far as can be done at this early date, the outlook for the building trades for the approaching season. While this first attempt has not resulted in as comprehensive a statement of the situation as we hope to be able to present in future years, it will, we trust, bear reading with a degree of interest and profit.

The year 1894 was undoubtedly the most inactive which the building trades in Canada have experienced during the last decade. The cause is known to have existed in the severe commercial depression through which this country and continent has been passing. It is now generally admitted that bottom has been reached, and that the tendency during the present year will be upwards.

The CANADIAN ARCHITECT AND BUILDER is grateful for the support accorded to it during the period of depression which is now drawing to a close, and hopes to merit a share of the increased prosperity which we believe to be in store in the near future for all connected with the building interests. Indulging this belief we are with more assurance able to wish every reader a happy and prosperous new year.

A RECENT conversation with the manager of one of our largest manufacturing companies, served to indicate to some extent the prospects for the heating trade the approaching season. "Our repair business last season was the heaviest we have ever experienced," he said, "the attempt was made to fix up all sorts of old heating apparatus to the extent necessary to make it do duty for another winter. This leads me to anticipate a brisk demand for new heating apparatus next seasnn." There would seem to be good ground for this view of the situation, and we hope to see the anticipations of better times, not only in the heating trade, but in all other lines as well, in some measure realized before the close of the present year.

WE regret to learn that amongst those who suffered loss by the financial collapse in Newfoundland, are several Toronto contractors. After the great fire in St. Johns, several architects and twenty or more contractors went from Toronto to that city and found abundance of employment. Some of these contractors had completed their contracts and returned home before the financial crash came, but others were less fortunate, and have been caught in the storm There were only two banks in St. Johns, and when both of these collapsed, paper currency and securities were valueless. Gold became the only medium of exchange, and some of our Toronto friends who were well enough provided with paper money and securities, had not enough of the precious metal to pay their way back to their homes.

In view of the recent fire it is to be hoped that the city council of Toronto will see the wisdom of complying with the recommendation of the architect for an extra appropriation sufficient to cover the cost of fire-proofing the roof and corridors of the new city buildings. Mr. Lennox estimates that after deducting the saving in insurance, the cost of fireproofing the buildings to the extent mentioned would not exceed $30,000. This would mean a charge for interest of only $1,200 per year. Surely for the sake of so small an amount, the council will not refuse to protect a building, the cost of which will run into the millions. If a wooden roof is allowed to be placed on these buildings their destruction will be next to a certainty in case of fire being communicated to them from adjoining buildings.

THE indications point to the success of the annual convention of the Ontario Association of Architects to take place in Toronto on the 15th and 16th inst. Nearly one hundred drawings and photographs of buildings erected by members of the Association have been received by Mr. C. H. C. Wright, of the Department of Architecture, who has reproduced them on lantern slides in order that they may be exhibited for criticism at the convention. It is to be regretted that the designs submitted for this purpose are not representative of the work of a majority of the members of the Association. If the result of the experiment this year should be considered satisfactory, however, a more thoroughly representative collection will doubtless be obtainable for future conventions. The CANADIAN ARCHITECT AND BUILDER for February will contain a complete account of the proceedings of this meeting.

SOME LESSONS OF THE TORONTO FIRE.

IT is frequently the case that necessary public improvements come only as the result of a public disaster. The recent conflagration in Toronto is a case in point. The fact that the means for the protection of the city from fire were totally inadequate for the purpose, was well-known to the chief of the fire department and others who took the trouble to investigate the condition of affairs. The city council was urged to furnish the necessary fire equipment, but the matter was from time to time deferred, with what serious result is now seen. Since the fire, the statement has been published that Toronto is perhaps the only city of importance on the continent of America, which does not possess a number of steam fire engines. Montreal has a dozen or more. Detroit has eighteen, in addition to, besides chemical engines, while other American cities with a population only thirty per cent. that of Toronto, have from eight to twelve engines. It appears also that the water mains in the business district of Toronto are of too small diameter to furnish the necessary supply of water in case of a large fire such as the city has just experienced.

The first thing requiring to be done is to put the fire equipment of the city in a thoroughly satisfactory condition. Second in importance to this comes the necessity for a thorough revision of the city building by-law, with the object of preventing the erection of structures such as some of those which were destroyed in the recent fire, and which had so much to do with spreading the conflagration. It is not many years since the existing by-law underwent revision at the hands of the Council, but in the time which has since elapsed many changes have taken place in materials and methods of construction, so that what virtue the by-law may have possessed five or six years ago it cannot be said to possess to-day. Within the period mentioned there have been erected a number of large buildings, five, six and seven stories in height, the upper stories of which the firemen with their present appliances are powerless to reach. In the absence of a carefully prepared building ordinance, some of these high structures have been erected throughout of combustible materials. The roof of the Globe building for example is estimated to have contained not less that 20,000 feet of lumber. The interior of the Osgoodby building was wood throughout, even to the partitions and ceilings. In addition to the combustible character of these buildings, the Globe building at least, was looked upon as an unsafe structure. The upper stories, surmounting two or three stories of an old building formerly used as a warehouse, were carried on iron pillars, and the upper flours of the building were loaded with heavy machinery. It is by no means improbable that had fire not destroyed the building, it would at some future time have collapsed and caused large loss of life. This building was a type of cheap and showy architecture erected under the supervision of a firm of American architects, who, after securing all the work they could during the period of the boom, returned to their native soil across the line.

There are other buildings still existing constructed in much the same manner, which, should a fire break out in them, would burn out as quickly and spread destruction to adjoining buildings. One amendment to the building by-law should be that roofs of buildings above four stories in height must be of metal and other fire proof materials, and where galvanized iron cornices are used, they should be backed with brick and supported on iron brackets. The method of constructing such cornices with wood backing and hung on wood brackets is a dangerous one, as in case of fire the galvanized iron becomes heated to such a degree as to set fire to the wood, and thus a path is formed for the flames around the top of the building. The combustible material such as has hitherto been employed in roofs and cornices is carried by the wind to adjoining buildings, and in some instances to distant parts of the city, thereby greatly enhancing the danger of a serious conflagration.

The present by-law does not regulate as it should the thickness of walls, nor does it limit as it should the area between brick walls. As a result, many buildings, such as warehouses, have been erected with large floor areas and walls of insufficient strength. A valuable provision would be that such buildings must be divided laterally by brick fire walls. The value of such walls was clearly demonstrated in Messrs. Buntin Reid & Co.'s building, where a twenty-four inch brick wall dividing the building was the means of staying the progress of the fire, and doubtless saved the wholesale district of the city from being swept away.

Something requires to be said also with regard to the use of iron in substitution for wood as a supporting material for buildings. It is well known to those who have investigated the subject that heavy wood beams are better capable of withstanding fire than steel girders and steel or wrought iron pillars, unless the latter are thoroughly encased in fire proof material, such as porous terra cotta. To encase merely the supporting columns, leaving the girders exposed is of little advantage. This method might be of some use in case of a fire breaking out in the basement or the ground floor, as it would be the means of keeping the floor supports intact for a considerable time, thereby giving greater opportunity for the fire to be extinguished. In the case, however, of a building taking fire in the upper stories, it becomes valueless. It is to be hoped that when the building by-law comes up for consideration and amendment, the protection by fire proof material of all structural iron work will be made compulsory.

In the present loose conditions of affairs, it has been possible for an unscrupulous architect, by offering to put up a building of larger dimensions for less money than could be done by one who proposed to carry out his work in an honest manner, to secure work which under proper conditions would find its way into the hands of the better men in the profession.

We are pleased to observe that the Toronto Board of Trade have adopted a resolution calling on the City Council to amend the building by-law, and to establish a building department, at the head of which should be a person fully qualified to judge whether or not the plans for buildings proposed to be erected have been properly designed from a structural standpoint. The head of such a department should be one fully familiar with the strength of the various materials entering into the construction of buildings, as well as the proper methods of using them. There is need also for more frequent and thorough inspection of buildings in course of erection, in order that when the by-law shall have been properly amended, its provisions may not be disregarded.

Finally, there is need for legislation such as the Ontario Association of Architects is seeking to obtain, which would make it compulsory on architects to pass a qualifying examination, and show themselves to be equipped for the proper practice of their profession.

The authorities of the Louvre have been conducting a series of experiments as to the best background for sculpture, and have now decorated the galleries which contain them with a light red colour.

CHARACTER SKETCH.

WM. T. JENNINGS, C.E.

"Because I have neglected nothing."—Nicholas Poussin.

ONE of the men who has played an active part in the construction of public works in Canada, is Mr. Wm. T. Jennings, who was born in Toronto, May 19th, 1846. Mr. Jennings was educated at the Model Grammar School and Upper Canada College in his native city, and commenced his professional career as an engineer in 1869. He was then under Mr. Molesworth, and his first work was to survey the swamp lands of Grey and Bruce for drainage improvements. From 1870 till 1875 he was on the engineering staff of the Great Western Railway, which he left to enter the service of the Dominion Government. From that time forward Mr. Jennings' chief work, perhaps, has been in the line of railroad construction. Several important surveys and construction works in the Northwest, British Columbia and other parts of the Canadian Pacific Railway were made by him while in the service of the Government, the Construction Co., and the C.P.R. Co. From 1886 to 1890 he had charge of the surveys and construction for the C. P. R. in Ontario, and early in 1890 was appointed Engineer for the City of Toronto.

Whatever work Mr. Jennings has undertaken has been marked by thoroughness and complete mastery of his profession. Nowhere was this more apparent than during the two years he occupied the position of City Engineer in Toronto. The basis of the present arrangement between the city and the Street Railway Co. had its origin with Mr. Jennings, and not only the excellent character of the road, but also the revenue the city receives from it in the shape of percentages and mileage tax is largely the result of thought on the part of the late City Engineer. Toronto is proud of its splendidly paved streets, and this work was planned by Mr. Jennings during his occupancy of the office of City Engineer. It was a special study with him to give to Toronto a system of pavements that should not alone be attractive as public thoroughfares, but that would possess endurance and lasting qualities. Negotiations between the city and Bell Telephone Co., which resulted satisfactorily for Toronto, were also undertaken while Mr. Jennings was in the service of the city. He had planned a system of underground wires in connection with the electric light and telephone contracts, and had he remained in office would likely have brought these plans to completion. During these two years the esplanade matter came up for consideration and Mr. Jennings had to fight with his known determination the strong railroad corporations.

WM. T. JENNINGS, C.E.

His official connection with the city did not cover as great a length of time as citizens, desirous of the well-being of Toronto, would have liked. The fact is that Mr. Jennings was too independent and fearless an officer to suit many who at that time occupied the position of aldermen. They quickly learned that he was a man who was master of his business and could not be dictated to, or used by those who had their own little schemes to carry out. Of his own free will, and to the regret of the better elements in the Council, after occupying the position for about two years, he resigned, owing to the aldermanic body breaking faith with him by changing the by-law under which he took office. The past two years of Mr. Jennings professional career have been employed, to a large extent, in the construction of various short lines of railway throughout the province.

Personally Mr. Jennings is popular with all who have his acquaintance or friendship. He is ever ready, out of his wide knowledge of public affairs, to impart information to those honestly wanting information; at the same time he is too busy to rest comfortably under the intrusion of those who hold to a person in his position much the same relationship that the editorial bore does to the journalist in his sanctum. His career furnishes a capital illustration of the saying of Owen Feltham: "That man is but of the lower part of the world that is not brought up to business and affairs."

Mr. Jennings is a member of the Canadian Society of Civil Engineers, the Institution of Civil Engineers, the American Society of Civil Engineers and the American Association for the Advancement of Science.

THE TRANSMISSION OF HEAT.

HEATING a building properly calls into requisition not only practical every day experience in the business of pipe fitting and furnace setting, says the Pacific builder, but also a thorough understanding of the laws governing the production and the communication of heat. As heat is the force, so cold is the absence or diminution of this force. It is produced by a mode of motion through particles of matter, whether gaseous, solid, or liquid, and is communicated in three ways, viz: by radiation, conduction, and convection. The radiation of heat, of which the warmth of the earth is an illustration, is the transmission of heat from one body to another through gases, the heat always passing in straight lines and with great velocity. Conduction consists in the passage of heat from one particle of a substance to another through insensible distances. By convection we mean conduction and radiation, as when heat is carried from one point to another by moving particles in liquid and gases. It should not be forgotten that in liquids and gases there is very little, if any, conduction of heat, and that radiation does not warm the air through which it passes. But while heat is not transmitted from one particle to another in gases and liquids, but depends for dissemination chiefly upon the movements of the particles, it is readily transmitted between them and solids. This is the whole secret of many difficulties in heating, and explains the futile attempts on the part of many purely practical workmen to heat rooms without the necessary attention to circulation. When warm water, steam, or hot air is used it is absolutely necessary that a proper circulation is maintained so that every particle of air or water comes successively into contact with the heated surface of the furnace or radiator. Many persons cannot understand why their rooms, although "perfectly tight" are yet but partially heated, even with a great consumption of fuel. To understand it thoroughly it is only necessary to remember the theory of the communication of heat by convection. For just as warmth and fuel may be wasted by too much ventilation, so they may be also thrown away by a lack of it; and it is only the expert heating engineer, trained both in the practice and in the scientific theory of his business, who is fully competent to meet all requirements of modern house heating and guarantee satisfaction in every instance.

THE wood-carving industry, which was formerly very prominent and profitable in Switzerland, is beginning to arouse serious apprehensions as to its future. The business in the Oberland of the cheaper and lower grades of wood-carving continues to be remunerative, but the demand for the better class of work has fallen off very much. The sales to English customers, formerly very large, have been seriously affected by the competition of German and Austrian woodworkers. The institutions for teaching wood carvers in Germany, established some years since, are said to be well managed and attended, and their influence is fast telling on the Swiss trade. There is at present some Federal and very considerable Cantonal interest taken in the fostering of this industry; but there is a growing sentiment that it can be maintained against the rising competition only by the Confederation assuming a more direct and complete supervsion of it with more liberal subventions for training schools; that the assistance, local and general, is too scattered and imperfectly organized to accomplish satisfactory results.

LINCOLN CATHEDRAL.

By Eustace G. Bird

AFTER travelling through many Cathedral shires, spending much time in sight-seeing, sketching and measuring many old fabrics, I at last set foot upon Lincoln.

Lincoln Cathedral, it may well be said, as she calmly reposes on her "Sovereign Hill" and looking abroad over the wide plains below, has no rival among English Minsters. As seen from a distance, overshadowing scores of red-tiled roofs, standing out against the sky, it is almost perfect in outline, crowned by three noble towers, highly pitched roof, lofty gables and pinnacles and the general harmony of design catches and pleases the eye of the traveller at first sight, and when more closely absorbed and studied, proves itself more worthy of the deepest admiration.

For purity of design, harmony of its parts, and the delicacy of execution of its details, as regards moulding and carving, Lincoln presents the best example of an instructive as well as the most delightful school for the architectural student who desires to make himself thoroughly acquainted with the styles and master of the first rudiments and development of Early English Gothic. For those students and others contemplating an architectural trip to old England, for the purpose of studying the true principles of Gothic Architecture, I strongly advise them to spend most of their time in Lincoln.

From the Norman work of Remigius in 1074 A.D., in the Western facade, and through Alexander "the Magnificent," Hugh of Burgundy, William of Blois, Hugh of Wells and Robert Grosseteste, we reach the touching point of the highest development of Early English Gothic Architecture in the Angel Choir which was finished in 1280 A.D., and exhibits the refinement and elegance as well as a delicacy of finish which can hardly be paralleled.

The observer will see for himself in this Cathedral that each successive epoch of the thirteenth century Gothic Style is complete in and separate of itself and it is obvious that under such circumstances the whole development of the Lancet Architecture can be studied under the one roof with ease.

To return to the history of the cathedral, the first cathedral was erected by Remigius de Fécamp, the first Norman Bishop, on the removal of the See from Dorchester on the Thames, in 1074 A.D. Of this cathedral the only parts remaining are the central portion of the west front, with its three recesses, a fragment of the first bay of the nave and the semi-circle foundations of the apse in the east end. Remigius' work is characterized by stern and almost savage plainness. After a fire in 1141 Alexander restored the cathedral. As to the parts remaining we may ascribe to him probably the three western doorways, the intersecting arcade above the two side recesses of the west front, and the three lower stories of the western towers, with their elaborately ornamented gables facing north and south. These are in the Transition style of the Norman and the Early English.

The great epoch of change which substituted the present exquisite fabric for the plain and bold work of the Normans, began 1196 A.D., during the Episcopate of Hugh the Burgundian, after the cathedral had been shattered by an earthquake.

Under St. Hugh, the choir and eastern transept with a portion of the east wall of the western transept were built. These portions of the building are very remarkable, as affording the earliest known example of pure Lancet Gothic or Early English free from any trace of Norman influence.

During the successive Episcopates of William of Blois, Hugh of Wells and Robert Grosseteste the great transept was completed and the nave gradually carried westwards in the Early English style between 1203—1253. To the close of this period we may assign the two western chapels, the arcaded screen-wall of the west front and its flanking turrets, the vestry and Galilee porch. The chapter house, with its detached buttresses and centre roof column, also belongs to this period. The two lower stories of the central tower were built in 1237 during Grosseteste's Episcopate. The upper story of the tower was commenced under Bishop Dalderby in 1307 and finished in 1311 in the Decorated style. A spire of timber covered with lead surmounted this tower to a height of 524 ft., and was destroyed during a tempest in 1548.

Between 1255 and 1280 we reach the last epoch and stage of the Early English work at Lincoln, in the carrying out of the Angel Choir built on the east end. This may really be called the Transition between Early English and Decorated.

This addition, the gem of the building, consists of five bays—two included in the ritual choir and three forming the retro-choir in which stood the shrine of the saint, and under the east window the altar of Our Lady. It is an exceedingly exquisite work, belonging to the very best period of English architecture and executed with the greatest delicacy of refinement.

There was no substantial addition to the main fabric of the minster after the completion of the Angel Choir. The cloisters and vestibule belong to the Decorated style, 1296. Although small, they present a beautiful example. Of a later date the upper stages of the western towers were built, and in this work will be seen the Transition from Decorated to Perpendicular. The wooden spires, which once crowned these towers, were taken down in 1808.

The Chantry Chapels of Bishops Fleming, Russell, and Longland are of the Perpendicular style.

The library at the north side of the cloisters is a classical work by Christopher Dean, 1674.

THE BYSTANDER.

On another page of this number of the Canadian Architect and Builder is published a letter from Mr. Cecil B. Smith, of Montreal, in reply to certain comments from the Bystander on Portland cements, published in the December issue of this journal. Mr. Smith evidently desires, if possible, to weaken the force of the statements there made, by saddling the authorship of the article in question, on some interested or uninformed source. Let the Bystander say, that Mr. Smith is altogether astray in his conclusions on this point. The Bystander is not interested a particle in Canadian cements further than as a citizen and journalist to give encouragement to the products of the Dominion. Written by a member of the editorial staff of the Architect and Builder, there is no necessity that the articles of the Bystander should carry an individual signature. Still less fair is Mr. Smith's reference to the connection in which Mr. Wright's name is used in the discussion. What views are credited to Mr. Wright, this gentleman is prepared to assume.

× × × ×

Now as to Portland cement. Readers can judge for themselves how far Mr. Smith has answered with any degree of argument or fullness, what was said in this column a month ago. His present letter only adds force to the contention of the writer that Mr. Smith would apply to Canadian cements a line of criticism, that he studiously withholds from English cements. It was stated plainly in former comments on this question that Mr. Wright and the Bystander were one with Mr. Smith in their desire to have produced in Canada a cement of "uniform fineness and strength, which will answer severe specifications." What is asked is, that this same rule be applied to imported cements. The Bystander does not contend that Canadian cements are perfect in uniformity of grinding or burning. Defects in this particular exist, though they are being rapidly overcome. Mr. Smith, however, would leave the impression in his original article and equally so in his letter of this month, that these defects were common only to the home product, and not to the imported article. The Bystander gave a number of facts to show that English cements were wanting in these particulars, just as the Canadian cement, and which disprove the statement now made by Mr. Smith, that English and other makers turn out an article, which is not variable. The Bystander repeats his inquiries of a month ago: What about the thousands of barrels of English cement of the poorest class, brought to this country, and yet supposed to come from an English maker of repute? Why are English manufacturers of Portland cement organizing for the purpose of securing an article that will not be variable? Why should Canadian cements be singled out for criticism, when, as Mr. Wright has shown, they will stand a test easily of 5%, and others have run as high as 3%, 2½% and even 1%, where large proportions of English cements will not average 10%?

× × × ×

Canadian manufacturers will, no doubt, thank anyone for suggestions that will lead to improvement in manufacture, and the Bystander would be sorry to say anything that would lull them into an unconsciousness of mistakes they may make. In doing this, however, there can be no occasion to free their competitors in foreign fields of defects in manufacture in which they are alike culpable with Canadians, and in some respects, are more so.

EFFECT ON THE ST. LAWRENCE OF THE PROPOSED DEVIATION OF A PORTION OF ITS WATERS TOWARDS THE GULF OF MEXICO, BY THE CHICAGO CANAL NOW IN PROCESS OF EXECUTION.

By Chas. Baillairgé, C. E., Quebec.

I DO not know that I can better answer your request for a New Year article than in treating in a cursory manner the necessarily interesting question of the effect which the Chicago drainage works will have on the waters and commerce of the St. Lawrence.

The so-called Chicago Canal, to be 42 miles in length, 160 ft. wide and to draw 20 ft. of water, with a legal capacity of 600,000 cubic ft. of flow per minute, has now been under way for some time. Twenty-nine separate contracts have been let of one mile in extent each, and the canal is expected to be ready for drainage and traffic by the end of 1896.

No doubt the riparians of the Des Plaines, Illinois, and Mississippi rivers have been wedded to the scheme, which, were it simply one of drainage of the great city, would be objected to on account of its polution of the waters of these rivers, by the fact that the sewage is to be thoroughly diluted and rendered so to say inoffensive by such an accession to it of Michigan water as may make of the canal one of a commercial and maritime nature, the prospective profits of the trade overcoming the dislike which the riparians might otherwise have to their waterways being made receptacles for and conveyors of this wealthy neighbor's detribus.

I have just said that the canal is to run 600,000 cubic ft. of water per minute, or 10,000 ft. per second. On the other hand Niagara runs 18 millions of cubic ft. of water per minute from Erie and the upper lakes into Ontario and the St. Lawrence, or 300,000 cubic feet per second. The St. Lawrence flow will therefore, of course, be thereby diminished by one thirtieth, and this of itself will naturally decrease our waters by say one thirtieth of their depth; which even on the channel of Lake St. Peter, must tell against the present draught of ocean steamers.

But Chicago, whose population is now but two millions, or close upon, in the near future may and likely will swell to six millions in another half or quarter of a century, when the canal will have to be enlarged to take the then increased drainage from the city with its percentage of diluting waters from Lake Michigan, in a way to run fully three times the quantity at present legally permitted. And that it may not be inferred that this is a gratuitous supposition, I have to remind your readers that extension has already been provided for in effecting the specifications necessary for the right of way. The ultimate flow through the canal will then be likely 30,000 cubic feet per second, instead of only 10,000, and diminish by one tenth the Niagara outpouring, and also by one tenth the depth of flow of the St. Lawrence; though, by less, below Montreal, due to such tributaries as the Ottawa, the St. Maurice, the Richelieu and other side issues; thus seriously affecting the present possible draught of vessels through Lake St. Peter, with a demand by our friends of Montreal and westward for a further dredging of the channel by some 3 ft. or 10% to make good the loss in flow, to say nothing of the fact that other portions of our maritime highway from the Great Lakes to the Ocean must suffer in a like manner, by forcing us to go back to river craft of less capacity.

Western traders, eastern to Chicago, are beginning to open their eyes to this subject matter of discussion, and it is strange to me that the Montreal, Quebec, and other Chambers of Commerce and Boards of Trade have not as yet in any way alluded to the fact in their more recent transactions.

But as a matter of international concern, or of mere legal right, how can one nation rob another of its God-given resources, turn aside its waters into new channels, any more than in a city, a village, an individual can impound and cause to deviate the waters of any stream or any notable portion thereof, without having, as bound by law, to turn them back into the same natural bed or channel for the use of his next neighbors on a lower level.

And this is why in my last report to the Quebec City Council on the proposed scheme of turning the waters of river Caché into river Huron and thus into lake and river St. Charles for the purposes of our aqueduct, and thus stay complaints and claims for damages by parties below the Lorette dam; this is why, say I, I put the Council on its guard and recommend that our legal advisers be consulted as to whether by thus deviating the Caché from its present purpose of supplementing the Jacques Cartier, the decrease in flow of the latter may not give rise to the same interparochial or intermunicipal complications as those which we are now striving against on part of mill owners who, below the dam are sueing for damages on account of the alleged decrease in the flow of the St. Charles by the off-take of our city aqueduct. Again, in the same way as damages may be caused and sued for on the one river, due to a decrease of its waters, in like manner an accession to those of the Huron and St. Charles above the dam, may be taken advantage of to proffer claims on account of more deeply flooded and otherwise cultivable lands on the borders of these rivers; and if the levees along the Mississippi can hardly hold out as it is during floods, how will it be with the riparians of this now comparatively shallow river, as of the Illinois, when added to in a way to put proprietors along their respective banks to the expense of raising the dams in a way proportionate to increase of flow.

This, Mr. Editor, is, of course, nothing but a mere sketch, destined to cause other engineers to think the matter over and air their views on an important subject of enquiry.

CONCERNING CHIMNEYS.

Americans do not make much of chimneys as do most of the builders of European countries. The builder is not sufficiently honest about his chimneys. Either he gives them undue prominence, overloads them with decorated materials or he treats them as though he were afraid of them. The chimneys of Amsterdam are beautiful indeed and add greatly to the picturesqueness of that city. Likewise in Paris, while they are there treated in a way somewhat more decorative than is common to the rest of the world, they are handled in an honest way, no effort being made to conceal them, and their decorative work is that of artists. There is often the idea that the chimney should maintain a symmetrical relation to the rest of the building. However, in no section of the world do we find a high regard for symmetry in chimneys successful; on the contrary, we find the most beautiful chimneys in that part of the world where they are allowed to have largely their own way; coming out of a building in unexpected ways and decorated by the hand of an artist.—The Clay Worker.

TRIMMING JOISTS.

The efficiency of single flooring is materially affected by the necessity which constantly occurs in practice of trimming round fire places and flues and across openings. Trimming is a mode of supporting the end of a joist by tenoning it into a piece of timber crossing it, and called a trimmer, instead of running upon or into the wall which supports the ends of the other joists generally. A trimmer requires for the most part to be carried or supported at one or both of its ends by some of the joists, which are called trimming joists, and are necessarily made stouter than if they had to bear no more than their own share of the stress. Commonly it is found enough to make trimmers and trimming joists from ½ inch to 1 inch thicker than common joists. In trimming tusk tenons should be used, and the long tongue or main body of the tenon should run not less than 2 inches through, and be draw pinned and wedged, moreover, if it do not completely fill the mortise in the direction of the length of the latter. The principal objection to single flooring, says a writer in an exchange, is that sound readily passes through, the attachment of the boards above and of the ceiling below being to the same joists throughout. Another objection is the necessity of making the joists so thin, not to injure the ceilings, that they with difficulty receive the flooring brads in their upper edges without splitting. A partial remedy for both these disadvantages is found in a mode sometimes adopted of making every third or fourth joist 1 inch or 1½ inches deeper than the intervening joists, and to these ceiling joists are notched and nailed, or nailed alone. This, by diminishing the number of points of contact between the upper and lower surface, for the ceiling joists must be carefully kept from touching the shallower joists of the floor, is less apt to convey sound from one story to another, and allows conveniently thin joists to be used for the ceiling without affecting those of the floor. It clearly, however, involves the necessity of cogging the deeper joists down so much more on the wall plates on which their ends rest.—Carpentry and Building.

OLD TORONTO BUILDERS.

THE dead past has not much interest to many whose lot is with the living present. As Artemus Ward has remarked, however, there is a pleasure in reminiscences of olden times, whilst Professor Wrong, of the Toronto University, in his lecture of a few days ago, is doubtless right when he says that many mistakes of the present would be avoided if people were better acquainted with the history of the past. "History is philosophy, teaching by examples," as another writer has said.

Though untempted to delve deep into the buried past there are few who have not an interest in that particular past which relates to their own selves or their individual callings. This has been the thought of the writer, as he has allowed memory, and historical incident and data, to take him back to the days when Toronto was best known as Muddy York, and the magnificent buildings which are the pride of her citizens to-day were unknown.

To make a start at the beginning of the century there came to York in 1800, Caleb Humphrey, a carpenter, builder and contractor. He was one of the pew holders of St. James church from its commencement in 1803, and pioneers whose memories will enable them to locate the south-west corner of Toronto and Adelaide streets, as it existed in those days, will remember Caleb Humphrey's house. More strictly speaking the late John. G. Howard, to whom the city owes a debt of gratitude for his handsome gift of High Park, ranks as an architect, rather than a builder, and yet many of the early houses of Toronto were built by him. The first 11-in. plank sidewalk on King street was laid by Mr. Howard. He designed the spire on St. Paul's church, Yorkville, in 1841, the work on which was performed by Mr. John Ritchey, the framing by Mr. Wetherald and the raising was superintended by Mr. Joseph Hill. This was one of the curiosities of the time and received significant mention in Dr. Scadding's "Toronto of Old."

A list of the inhabitants of York in 1805 includes in its numbers William Cooper, a builder, and owner of one of the first wharves and warehouses in York. Collin Drummond was a builder, and owner of a lumber yard, located on Yonge street, between Wilton avenue and Shuter streets, the burning of which, with other properties, is still fresh among the boyhood memories of the writer. Henry Hales was a builder and contractor of the first decade of 1800. He had a brick yard at the south-east corner of Duke and George streets. William Smith was a builder, who came to York with Governor Simcoe, and was the first man to take up a building lot after the laying out of the town plot. This was located at the north-east corner of King and Sherbourne streets, and the house which he built is still standing there. William Smith, jr., was a son and a builder. The boys of Toronto, who on Saturdays tramped out Yonge street to Hogg's Hollow, remember well the Severn brewery on Yonge street. This building was originally built by the father of the present John Baxter.

The recent burning of the new Globe building brings to memory the old Globe building, from which was published that journal, when some of us were boys in our teens. It was familiarly known as Dallas' building, and was situated on the property where now stands the Canadian Bank of Commerce. Let us go back, however, of the days when the printing press performed its mission on that site, and it will be remembered as the spot where stood in 1818 the first Methodist church at York. This remained a place of worship until 1833 when it was converted into a theatre. A memento of this church building is to be seen in a walking stick made from a portion of the altar rail by one who in those days was known as "Old Daddy Petch," and which later came into the possession of Mr. Robert Carroll, one of the best known contractors of the present day. Mr. Petch built the old church in question and at one time was a partner of ex-Mayor Manning. By the way, I am reminded that Mr. Carroll is to the manner born, being of the fifth generation of builders, bearing the name of Carroll. The history of the Globe corner of later days is well-known. The old buildings were afterwards supplanted by the fine warerooms of Jakes & Hay, furniture manufacturers, to take their place later by the Bank of Commerce.

The firm of Metcalfe, Forbes & Co., or as they were sometimes known, The Company, were builders of the old Bay street Presbyterian church, situated on the corner of Richmond and Bay streets, and of which the Rev. John Jennings, D. D., was for many years pastor. John Ross Robertson, in his Land Marks of Toronto, tells the story that early in the sixties a great storm occurred in Toronto, and one of the stone pinnacles at the south-east corner of the church was blown down and fell through the roof. The stone in its flight downward detached a piece of wood with a nail in it, which also fell, the nail piercing a Testament in one of the pews and punctured the book through to the text: Mark 7-25, "And the winds blew and beat upon that house; and it fell not; for it was founded upon a rock." The firm of Metcalfe, Forbes & Co. were also contractors for Trinity College and other prominent buildings. James Metcalfe, of this firm, was well-known to many as California Metcalfe, from the fact that he went off to that country and returned to Toronto a rich man, having struck it right in the gold diggings or elsewhere.

Messrs. Ewart & Parkes and Mr. Joseph Turton are known as the contractors of the old Parliament buildings. McDonald & Young make claim of having built the present city hall in 1845. The College avenue of a quarter of a century ago, was different from the College avenue of to-day and was a favorite excursioning point for the boys of that time. I can well remember the spot known as Sleepy Hollow, the residence of the Hon. John Beverley Robinson. This well-known residence was built by Mr. George Shaw, father of Ald. Shaw, and was the first building he ever put up.

The contractor for the masonry work of Knox church, Mr. J. Grant, was a familiar figure in building circles more than 25 years ago. He was known as Tam O'Shanter, because in addition to his business as a contractor he kept a tavern near Duchess street, to which he had given this name. The carpenter work of Knox church was done by McBean & Withrow, the latter the father of the present John Withrow. The gas office, the building of the Trust and Loan Co., and other commercial buildings, were erected by A. Burrowes, who was a contractor of prominence in Toronto 30 years ago. John Plenderleith's carpenter shop on the corner of Elizabeth and Edward streets, taking in the larger part of a square, gave employment to many men in the trade, who are still to be met on the streets of Toronto. An old builder of those days, who keeps active in the service, despite advancing years, is Mr. Wm. J. Hughes, a resident of Simcoe street. He came to Canada in 1832. It may have been forgotten by many citizens that Mr. James Dobson, late post-master at Yorkville, who died at the age of 85 years in December last, was a carpenter and carried on building operations in the city for a number of years.

One of the best known builders of more recent years, and yet an old-timer, was Mr. John Ritchey, who built Ritchey's Terrace, a row of houses on Adelaide street, between Bay and York streets, some of which are still standing, though ancient looking. He was born in 1796 and came to this country from Belfast, Ireland, in 1819. He died April 30th, 1866. He built St. George's church, St. James Cathedral, twice, before and after the fire, Judge Haggarty's residence, Simcoe street, the old Lyceum for French on King street w., the Dominion Express Co.'s offices, Yonge street, and his last work was the Dilworth house, on Jamieson avenue. There are a few men in the building trades to-day who remember John Ritchey, and his name suggests to them interesting incidents in the methods employed by contractors in ye olden days.

No sketch of the old builders of Toronto would be complete without a reference to John Harper, father of George Harper, a well-known Toronto architect of to-day. John Harper was a son of Richard Harper, who left Belfast, Ireland, for New York, in 1810. The father remained a resident of that city until 1817, when the family removed to Toronto, and Mr. Richard Harper entered into the building business. John Harper, the son, followed the father's calling and built St. Michaels Cathedral, Trinity Square, the first General Hospital, the first Toronto Observatory and laid the foundation of the present asylum buildings. He also built what is now known as the Newsboy's Home, a building intended at that time for the Canada Company's offices. The first depot of the Northern Railway was his work. John B. Smith, founder of the firm of J. B. Smith & Sons, lumber merchants, Toronto, and who died in March last, was a contractor, rather than a lumber merchant, in his early business days.

This much about old Toronto builders. The story is by no means exhausted. The digging process is an interesting one and much more could easily be unearthed. This task I may take up at another time, or what is not unlikely, enough has been said to prove suggestive to others, who will avail themselves of the opportunity the ARCHITECT AND BUILDER offers to supplement these reminiscences out of their own knowledge.

HOT WATER HEATING.

The hot water method of house heating is undoubtedly growing in popularity, both with the people and the dealers all through the country. Some idea of the extent, says the Building Register, can be gained from a well defined impression that exists that one-half of the radiation turned out by the manufacturers last year was for use with hot water. Preparations in a number of foundries this year have been made to supply a large demand for radiators for hot water use, both direct and indirect. People who have experienced difficulty in heating some rooms readily accept hot water as a means of heating, when it is explained that the radiator will be hot and throw off its heat in the apartment where it is located, no matter from what quarter the wind blows. The principle of the circulation of hot water is readily grasped by steam fitters, and the details of the pipe fitting can be learned much easier than the apportioning of the proper amount of surface for a given room.

ARCHITECTURAL REMINISCENCES.

A BRIEF HISTORICAL SKETCH OF THE LEADING ARCHITECTS OF TORONTO AND THEIR PRINCIPAL WORKS FROM 1842 DOWN TO THE PRESENT TIME.

THE first regular architect was Mr. John Young, a Scotchman, whose principal work in Toronto was the east wing of what was to have been the University of Toronto. This was erected in 1842, and was a bit of nice Edinburgh Classic work, in cut stone. The scheme was abandoned, and the building was used for some years as a branch lunatic asylum, and afterwards taken down to make way for the new Ontario parliament buildings. Mr. Young died in 1860.

The next architect was Mr. H. B. Lane, an Englishman, who designed the present City Hall and St. George's Church, in 1845, Little Trinity Church in 1846, and Holy Trinity Church in 1847. Mr. Lane returned to the Old Country.

The same year in which Mr. Lane arrived in Toronto witnessed the arrival of Mr. Kivas Tully, a native of the Emerald Isle—a man of good training and ability in his profession. His work was mainly in public buildings, such as the old Custom House, 1845, old Bank of Montreal, same year; St. Catharines Town Hall and Market, 1848; Trinity College, 1850; Welland Court House, 1851; Victoria Hall, Cobourg, in 1856. In the same year he was put in charge of the Toronto Lunatic Asylum and erected new wings and hospital to same in 1867 to 1870. In 1868 he was appointed architect, engineer and chief officer to the Department of Public Works. The public works reports furnish a fair idea of the number of these works passing through his hands, the latest of which is the Asylum for the Insane in course of completion at Brockville Mr. Tully, although well advanced in years, is still the picture of health, and fills well the demands of his onerous office.

Mr. John Tully, brother of Mr. Kivas Tully, came to Toronto in 1843, and after practising for a number of years here, moved to Chicago in 1868, and thence to New Mexico, where he died.

In 1847 a very important acquisition was made to the profession in the person of Mr. Wm. Thomas, architect, who had emigrated to Canada with his family. (A brother of Mr. Thomas was a well-known architectural sculptor in England for many years.) After the great fire here in ——, Mr. Thomas was entrusted with the rebuilding of the St. Lawrence Hall Market Block, which stands a monument to his taste and skill. He also designed Knox Church on Queen street, and the United Presbyterian Church, corner of Bay and Richmond streets, where the Medical Council building now stands. Many handsome shops and residences also give evidence of his skill and taste. Mr. Thomas' two sons, William and Cyrus, were associated with him for several years, and after his death, William settled in Montreal and Cyrus in Chicago. Mr. W. G. Storm was a pupil of Mr. Thomas, and imbibed much of his classic spirit.

Messrs. Cumberland and Storm, both well trained and capable men in their profession, filled a large space from 1847 to 1892 in the architectural progress of this province, and especially of the city of Toronto. St. James Cathedral, 1851; the Normal School Buildings, 1855; Old Toronto Post Office—now the Deputy Receiver General's Office; many county buildings; Toronto University and Osgoode Hall—both of these for many years being considered by visitors the best of their class on the continent.

Mr. Kaufman, a German architect of ability, came to Toronto in 1855. The Bank of Toronto and the Rossin House are samples of his work.

Mr. Joseph Sheard, with his son-in-law, Mr. Wm. Irving, enjoyed for many years a large and lucrative practice. Mr. Irving had the advantage of a good training in Scotch classic work, and their works, both public and private, were of the best class.

Mr. Matthew Sheard, son of Mr. Joseph Sheard, practised both here and in foreign cities, but has now retired from business and is enjoying the fruits of his ability and industry.

Mr. Henry Langley has been connected with the profession for a period of forty-one years, during the greater part of which time he enjoyed a large and lucrative practice, and from whose office a large representation of the present practitioners of the city and province has gone out. Among these are his nephew, Mr. E. Burke, Mr. Frank Darling, Mr. H. B. Gordon, Mr. Post, &c. Many of the largest and most costly churches in the city have been erected from his designs. The completion of the exterior of St. James Cathedral, as also of St. Michael's Cathedral, were his work.

Mr. James Smith, of the firm of Smith & Gemmell, who was contemporary with Mr. Langley, is now practically retired from business, enjoying the fruits of his toil and occupying himself with art and the work of the Royal Canadian Academy.

Mr. David Roberts, who for over thirty years enjoyed a lucrative practice, has now retired.

The new race of architects are now making their history. The new condition of things in the way of development in size of buildings, methods of construction and character of materials, will no doubt produce greater surprises than any in the past.

BOW WINDOWS.

MR. S. Smirke, R.A., remarks: "The bow window, as a peculiarly English feature well deserves our regard and attention. Though so cheerful and pleasant a feature in dwelling houses, it was, perhaps, in its origin designed not only for light and prospect, but also as conducive to security in troublous times, as a looking-out place; giving a wider area for observation than would be awarded by an ordinary window. We see the idea of a bow window carried out, although somewhat timidly, in the Border castles of the North. Subsequently, however, in Tudor times, when castles began to lose their frowning character, indicating a greater sense of security, and a desire to render home not only a place of refuge and defence, but also, to some extent, of domestic enjoyment, we then find them, as at Berkeley Castle, Kenilworth, and many other examples, assuming that particular character which afterwards became one of the principal attractions of an old English mansion. Indeed, we are justified, I think, in claiming this agreeable architectural feature as peculiarly English. Bow windows, no doubt, occur in some form or other in various parts of the Continent, scarcely even, perhaps, in Italy; not very commonly in France; but in Germany some types of the bow window are, I admit, common enough. At Furemburg, that great mine of picturesque architecture which every architectural student should visit and study, some particularly beautiful examples occur. Still there is a manifest local character that distinguishes all these German examples from the genuine old English manner of designing them. The Germans never appear to have so entirely departed from the ancient Gothic type as we find to have been the case in English domestic buildings. Their bow windows are apt to look more like perforated towers than with us; and there seems to have been retained a special disposition to place them at the angles of their houses, as if covertly intended to command the sides of the building, as the bastion of a fortification commands the curtain. Our Tudor bow windows, on the contrary, seem more designed for interior domestic enjoyment. As Bacon says of them, 'These be pretty places for a conference,' and it is certainly obvious that our ancestors, in building these bows, were far more bent on providing means for the pleasant occupation of a room than on producing any ornamental exterior effect. It is true they are always extremely picturesque, and never fail to contribute to the beauty of the building of which they form a part; but this only tends to prove what on former occasions I have repeatedly urged, that in design whatever is peculiarly fit and proper for its individual purpose rarely fails to be agreeable in its appearance."

COLORING METALLIC SURFACES.

A beautiful soft bronze color is now imparted to metals, says the Master Steam Fitter and Heating Engineer, by rubbing with a mixture of bloodstone and graphite, the application being made with a brush. Antique green effects are secured by dipping the metal into a solution of ten parts by weight of salt, ten parts cream tartar, ten parts acetate of copper and thirty parts carbonate of soda in 200 parts of vinegar. The satin finish is produced by green vitriol of copperas and subsequent treatment with wax.

Notice of dissolution of partnership in the firm of Gauthier, Vincent & Dufresne, architects, Montreal, has been filled and a new partnership registered bteween A. J. Vincent and L. A. Dufresne.

BUILDING IN CANADA IN 1894.

A Review of the Year's Operations in Leading Cities of the Dominion.

THE GENERAL SURVEY.

THE review of building operations in Canada for the year just closed, which we are enabled to give below, furnish readers with a fair conception, at least, of the conditions of the building trades in various parts of the Dominion. In a few cases the data that has come to us shows that an increase in building operations has taken place, but an analysis of conditions generally tell of a slow year for building. An increase at some points has taken place in the erection of dwellings for residential purposes. It is to be noted in regard to these, as also in the erection of business properties, that brick and stone are, in most cases, supplanting other materials for building. Even in cities like Winnipeg, and on the Pacific coast, where lumber is the natural product, brick is coming into enlarged use. There has been little done in the line of public works during the year, indicating, apparently, economy on the part of municipalities and governments, as much as individuals. This is a step that, while commendable in some respects, may yet be carried too far, and prove an injury, rather than a help, to the communities where exercised. Wise judgment needs to go with every attempt at economy, and it is to be remembered that the refusal to spend a dollar is not always a saving of that dollar. The labor market has undergone less change during the year than might have been expected, when one considers the depression that has existed in the ranks of skilled and unskilled labor. In the case of the former wages are fixed by the unions; and even though conditions would not permit of paying the highest wage, yet by these regulations men have been debarred from taking a smaller wage when work was offering them. This is one of the features of trade unionism hard for business men to understand when the situation compels a shrinkage in values and calls for a lessening of expenses in every other way. A hopeful feeling exists in regard to 1895, a condition that it is devoutly to be wished may be realized.

MONTREAL, QUE.

Architects and contractors complain with reason that the past year has not been brisk for them. Since 1890 there has been a steady decline in the volume of building operations, as the figures show. In 1893, which was not considered very good, there were about 1000 permits issued, while in 1894 only about 500 were issued, with an aggregate value of $2,750,000. The best year for the building trade in Montreal was 1889, when about 1800 permits were granted.

Although few in number, the buildings put up during 1894 include some of the finest erected in recent years, many of which will rank as architectural landmarks. There is also a decided improvement in the style and finish in all classes of buildings, but more especially in the three-storey stores and dwellings found on all business thoroughfares.

The widening of Notre Dame street has furnished the bulk of business to architects and contractors, as, had it not been for the rebuilding of that street, Montreal would have witnessed the poorest year of building operations ever recorded in its annals. All the buildings put up on that street are three stories in height, the ground floor being devoted to stores and the two storeys above to dwellings, and of pretty much the same type as those recently erected on St. Lawrence Main street, with the exception of a slight improvement in design and a more free use of stone. All are built with stone front, without mansard or peak roof, as the law governing that street states that they shall be built of stone and of no less than three storeys, without mansard or peak roof. Exception has, however, been made in the case of the new west end branch of the Merchants' Bank of Halifax, who are building, under the superintendence of Mr. Edward Maxwell, a substantial building built of sandstone and buff pressed brick, instead of entirely of stone. The building is four stories high, ground floor being occupied by the bank and the balance by tenants, with a handsome balcony on the top storey, decorated by Corinthian columns and the whole crowned by a Renaissance cornice, all of stone.

On the opposite side of Seigneurs street, on the corner of Notre Dame street, the Bank of Montreal is also putting up an elegant building, to be occupied by their west end branch. The building is entirely constructed of red sandstone, three stories in height, with a peak roof, but sloping towards Seigneurs street, and with a monumental gable facing Notre Dame street, decorated with Romanesque bas reliefs. This building is under the direction of the architects of the Bank, Messrs. Taylor & Gordon, who have just completed the Montreal branch of the Bank of Toronto.

Messrs. Perrault & Lesage have also built a branch office for the "Banque d'Hochelaga," and sixteen other buildings for various citizens on that street. Messrs. Perrault, Mesnard & Venne have built a dozen buildings on the same street for the estate of the late Hon. C. S. Rodier. Mr. W. McLea Walbank has also built fourteen buildings of the same class.

Amongst the public buildings erected this year the branch of the Bank of Toronto standing at the corner of McGill and St. James streets is the most important of all. It is built of sandstone, five storeys in height, well proportioned and richly carved. The building is a decided credit to the architects, Messrs. Taylor and Gordon; the sculptors, Messrs. Holbrook & Mollington, of Toronto, and the contractors for the masonry, Messrs. Whighton & Morrison. The porch forming the entrance to the banking room is profusely carved in the Romanesque style, and bears over the centre of two fine Tennessee marble columns the coat of arms of the city of Toronto. The interior is highly finished in marble and mosaics. The ground floor is utilized by the bank and the other storeys are laid out as offices. The six storey building of the "Banque du Peuple" comes next. Although not being an entirely new building—as the walls of the ground floor in the old structure were preserved—it might be considered as new, as no trace of the old structure is visible inside. The building is constructed of limestone; on the ground floor is located the banking room, which is entered by a large entrance porch, and which in proportion is about similar to that of the New York Life Building, which is situated opposite. The upper storeys are laid out as offices, all of which are admirably well lighted; in the centre there is a large light well running the full breadth of the building, elegantly finished in wood and painted in white enamel, with a gallery running all around at each storey. The cost of the building was $160,000, which is very low, if we consider the extent of the work done. The architects were Messrs. Perrault, Mesnard & Venne.

The Street Railway Company are building a six storey building at the corner of Place d'Armes Hill, Craig Street and Fortification Lane—built of limestone—to be partly used by the company and partly laid out as offices. Work has been at a standstill since its recent collapse, and has passed from the hands of a Montreal architect into the hands of Mr. Post, of New York.

The Birks block on Phillips Square is one of the many business blocks put up by Mr. Edward Maxwell; it is four storeys high and built of sandstone.

The Masonic Temple now going up on Dorchester street—future home of that confraternity—was won in competition by Mr. David R. Brown. It is four stories high, the ground floor being built of sandstone and the other stories above of buff pressed brick, contrasting singularly with the surrounding buildings, which are all of red brick.

The Murphy dry goods store is one of the most extensive business establishments put up this year. It is situated on St. Catherine street, is five storeys in height, built entirely of red sandstone, and was designed by Messrs. J. W. & E. C. Hopkins.

St. Antoine Market at the corner of St. James and Mountain streets, as the result of the fire of which it was the victim last winter, had to undergo a complete renovation. This task was entrusted to Messrs. Maurice Perrault and Eric Mann, who have jointly prepared the plans and superintended the construction.

Amongst the ecclesiastical buildings put up this year Erskine Presbyterian church is one of the finest. It is built on Sherbrooke street, in Deschambault limestone, with a graceful tower on the angle. The principal exterior feature is a large arch, half of its diameter being pierced by foliated lights in stone. The architect of this church was Mr. A. C. Hutchison, R.C.A. Knox church on Dorchester is another of the additions to ecclesiastical architecture that deserves to be mentioned. It is built of limestone and covered with a roof of conical shape, crowned by a lantern. The church has a seating capacity of 1200, and was designed by Mr. Edward Maxwell. Messrs. Brown & McVicar have put up the Taylor Presbyterian Church on Papineau Road—built of Scotch fire brick—with a seating capacity of 800. An important addition to St. George's Church (the finest church in the city after Christ Cathedral) was made during the year. The main tower, which had been left uncompleted at the level of the eaves of the roof, was completed under the direction of Messrs. Dunlop & Heriot, who have well succeeded in designing the tower in harmony with the architecture of the church.

The number of educational institutions has been augmented by three very important additions, viz.: The Seminary of Philosophy, five storeys in height, 300 feet long, with two projecting wings of 95 feet. The building is in the Renaissance style, built of limestone and situated on Sherbrooke street west. It cost in the neighborhood of $300,000. The Sacred Heart Academy on St. Alexander street, opposite St. Mary's College, is one of these three. The Academy is also a very large building and cost about $180,000. The chapel, which is very large, forms the central feature, and the class rooms are housed in two large wings on each side of the chapel. The other is the large building now being built on St. Denis street for the Laval University, which is also of limestone, four storeys high, and similar in its layout and proportion, to the new Board of Trade building. Its cost will be in the neighborhood of $200,000. Messrs. Perrault, Mesnard & Venne were the architects for these three institutions—the latter having been obtained in competition amongst forty competitors. Mr. A. C. Hutchison has also put up a substantial Academy at Cote St. Antoine, built of pressed brick.

The residences put up this year were not very numerous, but very good buildings were erected, amongst which are the residence of Mr. E. S. Clouston, of the Bank of Montreal, on Peel street, by Mr. Edward Maxwell; the residences of Messrs. C. Meredith and D. McIntyre on the same street and by the same architect, and the residence of Mr. Jas. A. Gillespie at the head of Stanley street, which has been designed to meet the owner's fancy for an old-fashioned English brick house, a desire which has been very successfully carried out by the architects, Messrs. Jas. and H. C. Nelson. Mr. Robert Findlay has also designed a house of quite artistic appearance in the Gothic style for Dr. D. F. Gurd, on Bishop street. Mr. W. McLea Walbank has also prepared the plans for the sandstone residence of Alderman Costigan on Dorchester street. Mr. A. Raza is building two large costly residences—one for Ald. Dubuc and the other for Ald. Brunet, on Sherbrooke street—both in the French Renaissance style, and elaborately decorated.

The price of material and labor, skilled and unskilled, has naturally slightly declined, owing to the dullness of building operations.

We look forward to a bright season in 1895. Early as it is, it can yet be said that 1895 will certainly excel 1894. The passing of the Anger Bill which renders the proprietor of a building responsible for the wages of men and cost of material employed in the erection of his building, if they are not paid for by the contractor, even if the contractor has already been paid the whole of his contract, has done a good deal to curtail building operations in this city during 1894. The Building Inspector is of opinion that the past year would have been very much superior to what it has been had this law not been in existence, and he says that the sooner it is repealed the better. A delegation of Montreal architects and building owners waited on the Provincial Government last December to urge the repeal of the Act but nothing has been done so far.

TORONTO, ONT.

Though rather more than a million dollars were expended in building operations in Toronto during 1894, as shown by the building permits granted, published below, the invariable reply from architects and builders is that the year has been most inactive. The permits fall below those of 1893 by some $340,000. A comparison of the two years also shows that 82 brick dwellings were erected in 1894, at a cost of $265,400, as against 139 brick dwellings, costing $446,700, in 1893.

Toronto has not fully recovered from the building excesses of the boom period, and though the vacant houses that numbered several thousands a few years ago are filling up, there are yet sufficient of these to meet all demands of the population, which happily, despite commercial depression, continues to grow. It would be a mistake for these reasons to say anything that would give unhealthy encouragement to an extension of house building, and yet the impression prevails in some circles that not a few dwellings might be erected with profit to the owners. The remark has been made by a well-known city builder that there are a good many houses in Toronto of a character that ought not to exist, some wanting seriously, because of age, in sanitary requirements. Others were built in the height of the boom and are not fit places to live in, and if people could only be made to understand this they would forsake the imperfect and unfit-to-be-inhabited houses and rent properties which are not possessed of these faults. The reply has been made that with curtailed incomes many persons are obliged to reside in houses that otherwise they would not rent, the low rent being the only inducement. In the better houses, to which reference has been made, the extra value would be secured in the additional accommodation and healthfulness of the home, and such houses are to be had to-day at low rental. As a result of an exodus of this kind from the poorer to the better houses it is believed that a stimulus would be given to improved building operations, and the old and imperfect houses would be torn down and others erected to take their place.

Perhaps the most notable buildings of the year have been the large seven-storey store erected on the south-west corner of Yonge and Queen sts. for R. Simpson, and the fine premises on King st. for John Catto & Son. The former is down on the permits granted as representing $80,000. In some respects the building stands out unique among the many fine warehouses and stores in Toronto. The architect was Mr. Edmund Burke, and we are glad to be able to give in this number of the ARCHITECT AND BUILDER illustration and letter press description of this store. Langley & Langley were the architects for the Catto store, and at another date we expect to publish an illustration and description of it. Both buildings are suggestive of innovations, and modern ideas, in store building and it is noticeable in the new store in course of erection for Kent, jeweller, as also in other store buildings, that some of these fresher ideas are being embodied.

In church building there has been hardly anything new in the year closed, outside of additions and alterations to several of the churches. School building has been more in the line of additions than new buildings. The Fern avenue school in Parkdale, opened for occupation after the holidays, is the only building that stands out for special mention. Work on the Union Station, which is down among the permits of 1893 for $185,000, and helps to swell the increase of that year, was pushed ahead vigorously in 1894, and is represented in the permits of the year by $52,000. Though not singled out in the permits of 1894 the alterations and additions in the head office of the Imperial Bank on Wellington street occupies a prominent place in the work of the year. These alterations practically mean a remodelling of the entire bank and will cost from $30,000 to $35,000. Messrs. Darling, Sproatt & Pearson are the architects and have reason to be congratulated on the character of the work done.

It seems but fair to note the fact that whilst the large music hall erected by Mr. Massey, and the Fred Victor Mission Hall, another evidence of this citizen's philanthrophy, appear on the permits of 1893 for $60,000 and $50,000 respectively, that a large part of the work on both buildings was done in 1894, the Mission Hall, which went in excess of the proposed expenditure, not being completed until near the end of 1894. Work on the new Court House was also pushed ahead with improved energy in 1894 and gave increased business to the building trades.

Building materials have in sympathy with the shrinkage in values in every branch of business shown a tendency to weaken, and better properties for relatively less money were erected in 1894 than in some years previous, a fact that cuts some figure in estimating the value of the work of the year. There has been no lowering of the standard union wage in the leading building trades within the year, and yet the labor market has been just that dull that contracts have been taken at unusally low figures and by different methods this reduction in price has been in part levelled up in securing labor at a reduce wage. This disposition, born of the depression of the past few years, to con-

tract for work at prices that can present only a small margin of profit to the contractor, if not in some cases, actual loss, is a problem that gives concern to thoughtful men in the business.

Returns from the City Registry Office for the year just closed showed the total number of mortgages recorded during the year to be 2,133, and the aggregate amount of incumbrances, $6,188,449. The city, for the purpose of registry, is divided into the eastern and western divisions and the returns show that there were 213 more mortgages recorded in the eastern than in the western division, and a difference in the amount loaned of $2,413,125.

What is the outlook for 1895? This is a question that seemed difficult to answer up to the first few days of the new year. Architects could not report that any large business was ahead of them. There have been talked-of operations in different lines. A million dollar hotel for Toronto has been named, and will be considered at a public meeting to be held this month, but whether it will go on, it is a hard matter to say. It would certainly add encouragingly to the work of the year. It is unnecessary to say that every citizen was pained to learn on Sunday 6th inst. of the disastrous fire that swept away the Globe building, the McKinnon warehouse and other valuable properties in the business part of the city, and they were appalled when on Thursday night it came to their knowledge that a second immense fire had broken out, and before its ravages could be stayed that a number of large wholesale warehouses, in the vicinity of Melinda, Wellington and Bay streets had been destroyed. The total loss in buildings from the two fires will represent nearly $1,000,000. With hardly an exception it is to be expected that these buildings will be rebuilt. This, of course, will mean an unexpected increase to building activities in 1895.

BUILDING PERMITS, 1894.

		Cost.
82	Brick dwellings	$ 264,400
4	Brickfronted dwellings	4,100
6	Roughcast dwellings	7,000
24	Brick stores	63,200
48	Alterations and additions to stores	67,500
8	Factories and work shops	54,600
8	Additions and alterations to factories	15,300
5	Warehouses	25,700
5	Alterations and additions to warehouses	31,000
34	New stables and additions to stables	12,140
133	Alterations and additions to houses	85,860
5	New schools and additions to schools	53,500
7	Churches and additions to churches	15,600
6	Hotels and additions to hotels and breweries	17,600
4	Coal sheds	14,300
2	Car houses and additions	32,000
1	Chemical laboratory at University	58,000
1	Addition to Hospital	30,000
1	Freight shed	20,000
3	Parts of new Union Station	52,000
2	Brick towers, gas works	5,000
1	Large store for R. Simpson	80,000
9	Miscellaneous buildings	11,425
	Total	$ 1,620,125.

Total number of permits granted, 400.

BUILDING PERMITS, 1893.

139	Brick buildings	$ 446,700
9	Brick fronted dwellings	9,800
9	Roughcast dwellings	6,900
14	Brick stores	72,350
28	Alterations to stores	49 600
4	Factories	37,500
26	Additions to factories	73,710
8	Warehouses	112,600
6	Additions to buildings	30,200
27	Brick stables	24,100
4	Roughcast stables	590
139	Additions and alterations to buildings	68,040
2	Club buildings	19,000
9	Office buildings	29,775
3	Hotels and additions	12,100
3	Additions to churches	2,750
1	Addition to Registry office	16,000
1	Music hall	60,000
1	Mission hall	50,000
1	Addition to Haven	15,000
1	Railway station	185,000
1	Motor shop	30,000
8	Miscellaneous	10,000
	Total	$ 1,361,850.

Total number of permits granted 444.

OTTAWA, ONT.

The greatest dullness in building circles prevailed in Ottawa during 1894, and the business done showed a marked decline over that of 1893. Few new buildings were erected. The work done consisted principally of structural remodelling of old buildings. The work of greater importance that may be specially named is as follows: Young Women's Christian Association, $15,000; Maternity Hospital, $7,000; Grant's block, $18,000; Stavis' block, $11,000; Hayter Reed's house, $16,000; St. Andrew's church, improvements, $5,000, together with certain additions to the Windsor Hotel, the Bank of Ottawa, and alterations in the Perley block. The main work done throughout the year was under the direction of Arnoldi & Calderon, G. M. Bayley, F. J. Alexander, Gregg & Gregg, William Hodgson, M. C. Edey and James Mather. There appears to have been little, if any, difference between the cost of building materials in 1894 and 1893, and prices for labor have remained about the same. With a few insignificant exceptions the principal material used in building has been local stone and brick. Ottawa is not a place where speculative building is indulged in to any alarming extent, and yet each year a number of cheaply finished dwellings are erected by contractors on speculation, meeting, seemingly, the requirements of a certain class of the population. Time alone will tell what 1895 will bring forth; as yet no new work is in view.

HAMILTON, ONT.

The total value of permits issued in Hamilton for 1894 was $464,832, against $471,768 in 1893, showing a decline of only $7,136. It may, therefore, be said, that despite dull times the Ambitious City has held its own better than many other cities in the Dominion. The work completed has shown a goodly increase in residential buildings, with 18 business buildings and 4 public buildings. Among the latter can be included two schools, at a cost of $20,000 each, Mr. A. W. Peene and Mr. W. A. Edwards being the architects; House of Refuge, $22,000, R. H. Barber, architect; addition to St. Joseph's Hospital, $12,000, R. Clopecy, architect. The larger part of the work of 1894 was undertaken by the following contractors: Halliday & Webber, G. H. Mills, R. Press, Wark & White and Hannan & Jacques. The cost of building materials in 1894 was considerably less than in 1893. Labor, skilled and unskilled, commanded about the same price as a year previous. Not a little of the prosperity of Hamilton during 1894, and this likely explains the increase in the erection of residential buildings, is due to the Hamilton smelting works, located in the outskirts of the city, a concern employing a large number of workmen. Architects and builders look forward to a prosperous year in 1895.

LONDON, ONT.

Building operations in London for the years 1893 and 1894 have run about parallel with each other. The more important buildings erected in 1894 were: St. Paul's Cathedral, at a cost of $50,000; First Presbyterian Church, $25,000; remodelling the Huron and Erie Savings and Loan Building at an expenditure of $15,000. These buildings were designed by Spiers & Rohns, of Detroit, Mich. Tambling & Jones were contractors of the first named building, E. Martyn and W. Tytler of the second, and J. Haymon and Jones Bros. of the third. A large amount of residence building was done during 1894 and of a character that reflects credit on Moore & Henry, H. C. McBride, J. A. Gauld and George Craddock, home architects. It is to be noted that the heavier work of the year has fallen to American architects, and this disposition on the part of the people of London has been further aggravated in awarding the designs for the new Free Library buildings to Mr. C. C. Haight, of New York, though he has since established himself in business in London. Why should this be so with talent of the first order at home? The money that goes to pay for such edifices as St. Paul's Cathedral, the Presbyterian church and the Loan Society comes from the people of London. Prices of material during 1894 were considerably less than in 1893. The labor market has remained about the same. The prospects in building for 1895 are exceedingly encouraging.

OWEN SOUND, ONT.

The growing town of Owen Sound in 1894 did not fall behind the year previous in building operations, the figures for both years running about $35,000. The most noteworthy feature has been the erection of a considerable number of residential buildings of the decidedly better class. Only one business block of importance was erected in 1894. Brick and limestone trimmings have predominated in material employed. Prices of material were about the same in 1894 as in 1893. An unhealthy feature of the building trades has been the disposition in many cases to take work at abnormally low prices. Some contracts of the year were undoubtedly taken at a loss. This may be considered a good thing for the capitalist who is putting his money into

property, but taking a wider view, from the business standpoint, it is a feature of trade that in the end can only be productive of evil. Work in this locality commences, owing in part to a late spring, later than in some other places, which renders it difficult to say just yet what the prospects will be for the new season.

GUELPH, ONT.

The Royal City during 1894 showed a degree of activity in building operations that was common to few places. The volume of business done amounted to $150,000, which was about $10,000 in excess of 1893. These figures can be divided as follows: Residential, $61,300; business, $21,700; public buildings, $67,000. The erection of an opera house at a cost of $37,000, a large addition to the hospital, costing $30,000, and a block of stores for Thomas P. Coffee embraced the heavier contracts. The architects to whom was assigned the chief work of the year were H. J. Powell, Stratford, G. M. Miller, Toronto, and John Day, Guelph. Brick and stone have been nearly altogether used in building operations. There has been no change as compared with 1893, either in the price of material or labor. The prospects for 1895 are good.

BELLEVILLE, ONT.

About $100,000 is the figure that will cover building operations in Belleville during 1894, a slight decrease over 1893. Largely these have consisted of buildings for business purposes and the material used has been nearly altogether brick. Neither in prices of material or labor can it be said that the conditions of 1894 differ from those of 1893. No public buildings were erected during the year, calling for particular mention. A hopeful feeling exists regarding the new year, and it is expected that the volume of business done will exceed that of the year just closed.

QUEBEC, QUE.

Building records in the Old Capital for 1894 do not augur hopefully for the growth of the city. The volume of operations will not total more than about $500,000, about one half of that of 1893. This work has been largely covered in the erection of residential buildings of brick and stone. No buildings of sufficient importance have been erected during the year to call forth special mention. Prices of brick were lower in 1894 than in 1893, whilst stone and lumber have remained nominally unchanged. Wages commanded by bricklayers have been decidedly less than a year ago. Masons, carpenters, joiners and roofers have been paid about the same wage in 1894 as in 1893. With a retrospect as dull as that here stated, it is yet too early to make any reliable forecast for 1895.

ST. JOHN, N. B.

The year 1894 was one of extreme dullness in building operations in St. John, falling below the average of other years. No buildings of any importance were erected that could be singled out for special reference. There has been more or less in the line of repairing and the erection of a few low priced houses. What the new year will bring forth "no fellow can tell" yet.

HALIFAX, N. S.

More money was expended in building operations in Halifax, N. S. in 1894 than in 1893. About 130 buildings were erected, besides alterations and improvements to 40 others. These may be divided as follows: Residential 79, of these 6 brick and 73 wood; business 45, 14 brick and 31 wood; public 6, 1 brick and 5 wood. The buildings that stand out most prominent are: Roman Catholic Seminary, brick and stone, J. C. Dumaresq, architect, M. E. Keefe, contractor, cost $35,000; N. S. Furnishing Co.'s store, brick and stone, E. Elliot, architect, Rhodes Curry & Co., contractors, cost $30,000; Clayton's business block, brick and stone, J. C. Dumaresq, architect, John McInnis & Sons, contractors, cost $12,000; Roy's business block, brick and stone, S. H. Tremane, architect, T. M. Brookfield, contractor, cost $12,000. Prices of material in 1894 showed little change as compared with 1893. Wages of carpenters and laborers were about 25% less in 1894 than 1893. Prices of labor in other trades remained unaltered. The decrease in wages of carpenters may be accounted for, in part, from the fact that the depression in the United States drove many in this line to seek employment in the Maritime Provinces. On the other hand there was a scarcity of masons, as a good many were engaged in work in St. John's, Nfld. Prospects for the new year seem fair, though it is difficult to speak correctly until about April. Several good buildings are in contemplation.

VANCOUVER, B. C.

The year 1894 has held its own in building lines fairly well when compared with 1893. The total cost of buildings erected was, perhaps, a little less than that of 1893, but the difference has not been particularly noteworthy. Residences of the better class have run into fair numbers, though, generally, too many of these have borne the stamp of the speculative builder. Office buildings, rather than warehouses, have predominated among the business class. There has been little or nothing in the way of public buildings during the year closed, except what remained to complete of the court house, representing a cost of $40,000. The architect in this case was Mr. R. Mackay Fripp, F.R.I.B.A. Other buildings of considerable size are as follows: The Dunn block, cost $20,000, architect, William Blackmore; Hudson Bay warehouse, $30,000 to $35,000, architect, O. Wick; Bank of Montreal, (completed), Mr. A. T. Taylor, F.R.I.B.A., of Montreal, architect. In both the prices of material and of labor there has been a slight decline. Buildings, as a whole, in this new Pacific coast city, show a marked improvement in quality of workmanship, durability of material, and in a few isolated cases the designing and planing are far in advance of past years. The Bank of Montreal is the most noticeable example of this. With timber in rich abundance in British Columbia, residential buildings are almost entirely of wood. For business purposes brick and stone is coming into increased use. Brick with Portland cement facing and cornices is prominent in the public buildings of Vancouver. No one is over sanguine of the outlook for 1895; the indications at present point to a somewhat dull season.

WINNIPEG, MAN.

As is the case with most new and progressive cities Winnipeg has had a varied experience when viewed from the standpoint of architect and builder. It has had its boom, and its collapse. But of late years the growth of the city has been of a more steady and reliable character. The fact that the year 1894 was less favorable in building than 1893 may doubtless be accounted for by the financial depression that has existed the world over, and which has not left unscathed our own country. There was less building in Winnipeg in 1894 than in 1893. Few residences of any importance were erected, the work in this line being confined chiefly to cottages and houses of a small class. An unfavorable feature in connection with house building has been a manifest tendency to speculative building. Only disaster can follow the continuance of this method, and in the best interests of Winnipeg it is to be hoped that neither capitalists or building societies will allow themselves to encourage this line of work. Prominent among the more important buildings erected during the year have been the new court house, or rather its completion in 1894, at an expenditure of $53,000, and representing a total cost of $72,000. The Ottawa Bank was also finished during the past year. The total cost of the building was about $60,000, and rather more than half of this was expended on the work in 1894. The Davis block of stores was erected at a cost of $20,000; alterations were made in the Union Bank, amounting to $10,000; buildings for water works purposes were erected at a cost of $13,000. The architect of the buildings named was Mr. Charles H. Wheeler. There was also erected in 1894 St. George's Church (Episcopal), brick veneer and stone foundation; basement used for Sunday School purposes; cost $12,000; architect, Mr. George Browne. The Nurses' Home in connection with the General Hospital, solid brick and stone foundation, two storeys and finished basement and attic, was the work of Mr. McGowan, architect. St. Andrew's Church (Presbyterian) was erected at a cost of from $35,000 to $40,000; materials used, stone and brick; architect, J. McDiarmid. A work of marked importance in 1894 was the Wesley College, erected at a cost of $75,000; materials used, Calgary stone, backed with brick, slate roof; Geo. H. Browne and S. F. Peters, associate architects. Compared with 1893 no remarkable change has occurred in the labor market. Skilled labor command as good a wage as in 1893, whilst unskilled labor has shown a slight decline. Brick and stone were cheaper in 1894 than in 1893, materials in use in wood-work holding unaltered. Brick, stone and steel are coming into increased use in building in Winnipeg. Well informed authorities say that things at present are so dull that it is difficult to predict what will be the outcome of the building trades in 1895.

ILLUSTRATIONS.

STORE OF R. SIMPSON, CORNER OF YONGE AND QUEEN STREETS, TORONTO.—EDMUND BURKE, ARCHITECT.

THE premises cover a frontage on Yonge street of 118 feet, and on Queen street 157 feet, the corner, 70 × 100 feet, being occupied by the new building.

Building operations were somewhat hampered and difficult owing to the conditions and surroundings. Some of the heaviest traffic on the streets of Toronto is centered at this point, street cars passing up and down Yonge street about once a minute, and along Queen street at about double that interval. The foot traffic on Yonge street is also exceptionally great, and as the tracks are double on both streets, and turn the corner within a few feet of the curb, it was found necessary to provide a passage of ample width without encroaching on the roadway and permit at the same time the prosecution of the excavation under the sidewalk. This was accomplished by the construction of a raised bridge kept three feet above the level of the roadway, supported by shores, which were lengthened as the excavation was deepened. This bridge was covered in to form the usual hoarding for the protection of the public, and the whole was maintained till the completion of the building and also of the granolithic sidewalk beneath. The Queen street sidewalk for a length of 105 feet was fenced in, and most of the material was taken in through one or two openings. Long girders, etc., had to be taken in at night or in the short intervals between the passing of the cars. Business had also to be maintained in the Queen and Yonge street stores without interruption. To this end a complete wooden wall, dust and weather proof from cellar to roof, was constructed in these stores, sufficiently far away to permit of the removal of the party walls and to make connections of old floors to new beams supported from the columns carrying the new building. Some of the work was carried on night and day, chiefly the excavation and the structural steel works, the night work being done by the aid of electric lights.

STUDENTS' DEPARTMENT.

"C. A. & B." COMPETITION FOR A MUSKOKA COTTAGE.

THE judges in the above competition have submitted the following report:

"Although a great many designs have been submitted, this competition is not at all satisfactory. The competitors have exercised the greatest freedom in the interpretation of the conditions, but in spite of this not one of them has produced anything approaching an ideal "Muskoka Cottage."

"Ye Olde" has been placed first because in this design alone some artistic skill is evinced in the treatment of the elevations, but the planning is very weak. No advantage has been taken of the variation in levels in the site, and the avowed purpose of enclosing the walls of the two elevations not shown with siding, cannot be too strongly condemned.

> "Rearing our temple let it be our pride
> Nought to neglect, but build with patient care,
> A perfect building, finished everywhere;
> Not a mere facade with one good side."

A 12x22 room without a fireplace and with a stair and four doors opening off it, is not a "generous living room" for a Muskoka cottage, and the pantry would be very much better between dining room and kitchen. The 10x10 room with a stair reducing the height of one side to 4 ft. 6 in., lighted only from a window overlooking the front verandah, and labelled "bedroom," would be of very little use for that purpose, and there are not enough closets.

"Bydand" gets 2nd place by the ingenious manner in which he plans his bedrooms, but the verandah is much too narrow and would be much better without the rise of three steps at the west end. This difference in level, while it prevents an entrance to the verandah at the ground level, has the effect of reducing the privacy of the front bedroom. The fireplace in living room is very badly placed, and this room would be much better for a window unshaded by the verandah. The arrangement of doors to kitchen and pantry is bad.

"Eureka," which takes 3rd place, is unquestionably the most carefully thought out plan submitted, and would, but for the silly affectation of symmetry, in showing two stairs from the living room, both landing in the same spot on first floor and balancing the porch by the cloak room, have taken a better place. The idea of giving the whole of the ground floor to the living room and verandah, and taking advantage of the hillside site to get the kitchen department at a lower level is good and well adapted to the requirements of Muskoka life, but it would be better to have the dumb waiter larger, so that it could act as a sort of moveable pantry, as this would enable the removal of dishes, &c., from the living room after meals to be effected very rapidly and easily. The fireplace alcove is too near the door, and the cloak room too far from it. The bedroom floor is well planned, but a bath-room is hardly necessary in a Muskoka summer cottage. The flat roof would be an excellent place for a dance on a moonlight evening. Although excessively ugly, praise is due for the frank way in which the elevations are treated, and the drawing is good.

"Rosseau" comes in a good fourth, with a good verandah but very poor living room. The fireplace between the stairs and pantry door is utterly useless, and the cutting off of the internal corners of the living room is childish. The "den" would be better treated as a simple alcove off the living room. The bedroom floor is fairly well planned, but would be better if the little triangular closet were left out and the N. W. bedroom finished like the N. E.

"Gravenhurst" submits a simple plan, substituting dining room, reception hall and sitting room for the living room called for, but all the windows to these rooms are shaded by the verandah and the proportions of the elevations are not good. A fireplace and chimney built of boulders as shown in the section would be cumbersome and difficult to keep clean.

"Hunter" has a very good arrangement for his earth closet and the kitchen and pantry are fairly well arranged, but both living room and verandah are poor, and the bedrooms are not sufficiently lighted.

"Kenozsha" has a good living room but very poor verandah. The space between kitchen and ground floor bedroom would have been much better as one good pantry than cut up as it is. The bedroom floor plan is good, but rather too much space is devoted to the hall.

The work submitted, with perhaps the single exception of "Ye Olde," points to a familiarity on the part of the students with second rate examples of American design, but evinces little or no knowledge or study of the principles of true architecture, and we would advise the students to direct their attention to the study of better examples of architectural design. Osbourne's House Planning gives the principles of domestic planning in a very concise form, and examples of skilful and artistic design for small houses are to be found in plenty in the pages of the "Builder," "Building News," and other similar publications.

Most of the drawings submitted might, for any evidence of artistic knowledge they contain, have obtained their motive from some of the publications issued by the "Co-operative Building Plan Association" or other similar institutions, and if "the budding architect" cannot produce better work than this, the public can hardly be expected to go to the expense of architectural services for buildings of this sort.

S. H. TOWNSEND.
H. J. EDWARDS.
JOHN GEMMELL.

[The names of the winners of the competition are as follows: "Ye Olde," T. R. Johnson, 74 Baldwin St., Toronto; "Bydand," Kenneth Gordon, Toronto; "Eureka," J. Eugene Payette, N. Y. Life Building, Montreal.—EDITOR C. A. & B.]

BEARING POWER OF FOUNDATIONS.

FROM the valuable note-book of Mr. E. L. Corthell, of the Western Society of Engineers, we have been permitted to extract the following data respecting the bearing power of foundations.

Clay.—From 2 to 8 or 9 tons per square foot, without allowance for friction.

Sand.—The different kinds vary greatly in bearing power Sand mixed with loam will not bear more than 5 tons per square font. 9.3 tons per square foot were placed on fine gravel and sand at Urk viaduct: masonry piers on cylinders 4.8 inch diameter; friction neglected.

In India, on coarse sand in deep foundations, not over 9 tons are used.

In experiments 20 tons have been put on sand without measurable settlement.

Friction.—Side friction varies from 200 to 600 pounds per square foot.

All the above are in gross tons=2,240 pounds.—B. Baker April 17, 1888.

Clay.—Black Friars Bridge, 5 tons per square foot. Settled badly.—Randall Hunt, Engineering and Building Record, June 23, 1888.

New London Bridge, 5 tons per square foot on piles, =80 tons per pile. Settled badly.

Newcastle-on-Tyne, 1½ tons per square foot; no settlement.

Fargo, Dakota, four-story building, 2½ tons per square foot; failed. Then 1½ tons per square foot; no settlement.

Cleveland, new viaduct, 1 to 1.7 tons per square foot.

Washington Monument, 9 tons per square foot, inside edge. Clay and sand, 3 tons per square foot, outside edge.

Sand.—Coney Island pier, 5 tons per square foot.

New York Steam Company's chimney, 4 tons per square foot on fine sand; settled.

Brooklyn Bridge anchorage, 4 tons per square foot.

Nantes Bridge, 6.8 tons per square foot; settled.

Berlin, considered safe, 2.3 tons per square foot.

Sometimes used to 4.1 tons per square foot.

Albany Capitol, 2 tons per square foot; settled.

Cairo Bridge, fatigue weight:

Channel piers, 3.34 tons per square foot.

River Piers, 33.08 tons per square foot.

Friction on sides taken at 4,000 pounds per square foot; fine sand.

Sioux City, Pier III; sand, 2.64 tons per square foot.

Soft Soil.—India, one ton per square foot used.—Journal of Engineering.

SAFE BUILDING REQUIREMENTS.

IN view of the necessity for immediate revision of the by-law which is supposed to govern the erection of buildings in the city of Toronto, we print below the provisions of the building laws of the cities of New York and Boston regulating the thickness of walls of brick and stone buildings of varying heights:—

THICKNESS OF WALLS REQUIRED IN THE CITY OF NEW YORK DWELLING HOUSES.

HEIGHT OF WALLS.	THICKNESS. FOUNDATIONS. STONE.	FOUNDATIONS. BRICK.	EXTERNAL WALLS	PARTY WALLS.
Not exceeding 55 feet.	20″	16″	12″	12″
Exceeding 55′ but not exceeding 80′.	24″	20″	16″ to top of second floor, 12″ remaining height, if not more than 40′.	16″
Exceeding 80′	8in. thicker than the wall next above.	4in. thicker than the wall next above.	4″ thicker than the above for every 15′ added to the height of the wall above 80′.	16 inches.

BUILDINGS OTHER THAN DWELLINGS.

HEIGHT OF WALLS.	STONE.	BRICK.	BEARING WALLS.	OTHER WALLS.
Not exceeding 40′.	20″	16″	12″	12in.
Exceeding 40′ not exceeding 55′.	24″	20″	16″	12in.
Exceeding 55′ not exceeding 75′.	28″	24″	20″ to height of 20′. 16″ to height of 55′. 12″ remaining height	4in. less than bearing wall
Exceeding 70′ not exceeding 85′.	32″	28″	24″ to height of 12′. 24″ to height of 60′. 16in. remaining h'g't	
Exceeding 85′	8in. thicker than the wall next above.	4in. thicker than the wall next above.	4in. thicker than the above for every 15′ added to the height above the 85ft.	

THICKNESS OF WALLS REQUIRED IN BOSTON DWELLING HOUSES.

	THICKNESS. FOUNDATION. BLOCK STONE.	FOUNDATION. RUBBLE STONE.	BRICKS.	EXTERNAL WALLS.	PARTY WALLS.
Not exceeding 35 ft.	16in.	20in.	16in.	12in.	12in.
Exceeding 35 ft., not exceeding 55 ft.	18in.	22½in.	16in.	12in.	12in.
Exceeding 55 ft.	20in.	25in.	20in.	12in.	12in.

BUILDINGS OTHER THAN DWELLINGS.

HEIGHT OF WALLS.	THICKNESS. FOUNDATION. BLOCK STONE	FOUNDATION. RUBBLE STONE.	EXTERNAL WALLS.	PARTY WALLS SOLID.	PARTY WALLS VAULTED.
Not exceeding 35ft.	24in.	30in.	16in. to top of upper floor, 12in. remaining height.	20in. to top of second floor, 16in. to roof, 12 in. remaining height.	20in. from foundation to under side of roof boards.
Exceeding 35ft.	28in.	× × ×	20in. to top of third floor, 16in. remaining height.	Same as above.	

In Germany water pipes are being made of glass with asphalte covering, to prevent fracture. It is claimed that they give thorough protection against moisture in the ground, and against the action of acids and alkalies.

FIREPROOF FLOORING.

THE increased interest which has within the past year or two been shown in the construction of fireproof floors is indicated in a marked manner by the experiments, though small in number, which have been made for the purpose of testing the strength and fire endurance of concrete and hollow-tile flooring, as well as by other tests now contemplated. These evidences show that this class of construction is receiving an amount of attention which is destined to soon bring it to a much more satisfactory condition than it has hitherto attained. It is obviously easy and simple enough to construct a floor which will be both strong enough and essentially fireproof with either concrete by itself or with any of the rather numerous clay products in the shape of hollow terra-cotta or tile, provided it is not at the same time requisite to attain low cost and a minimum weight. As a matter of fact, up to the present time fireproof floors of the best quality and requisite strength are excessively heavy, as anyone must readily realize who has designed a modern high building of the skeleton type. The weights or loads under which the column sections are designed, are made up largely of the weight of the floors, which are dead weights in the most intense sense of the word. They add extremely little to the stability and stiffness of the building, but they add both directly and indirectly to the cost of the structure, and hence any kind of floor which is found to yield an increase in unit strength, as it were, and thus decrease total weight, cannot fail to be of material advantage.

The recent tests of a combined concrete and iron-wire floor, together with corresponding tests of flat and arched hollow-tile flooring recently made at Trenton and fully described in The Engineering Record of Dec. 22, show that the combination of metal and concrete possesses some characteristics of considerable merit in this connection. A number of combinations of the same materials and for the same purpose, as is well known, have for some time been advocated and even employed for fireproof floor construction, but we do not recollect that any quantitative tests of strength and resistance to fire have been made prior to those which have just been named. The two chiefly interesting features brought out by these tests were, the large reduction in weight (about 40 per cent.) over the hollow-tiled floors with which experiments were made and the apparent fire endurance of the combined iron and concrete. Sufficient data are not at hand to enable any reliable comparative estimates of cost to be made, but there seems to be no costly elements in either the material or processes required by the lighter construction, while its high load-carrying capacity certainly fills every reasonable demand for strength. It is obviously a necessity for the fire endurance of such a combination that the metallic portion should be well imbedded in the concrete, but having attained that end, it would seem that an essentially fireproof quality is attained.

It has been maintained by some engineers that the rates of expansion and contraction due to change of temperature would in a short time destroy such a combination, but it is now well known that the two rates for iron and steel and cement mortar or concrete are so nearly the same that for practical purposes they may be considered identical, and hence that there is no ground for criticism on this score. The whole field is one of no little structural interest, and the questions involved can be satisfactorily settled in no other way than by intelligently conducted quantitative tests such as those we have named and others now in preparation.—Engineering Record.

It is probable the Normans, after their arrival in England, adopted the dwellings they found in existence until the necessity of their removal, through decay, induced the re-erection of the buildings in an improved and more commodious form, and it began to be found that the repeated destruction by fire of the frail tenements of their predecessors induced the necessity of a change in the material of the houses. Accordingly, in the twelfth century stone with shingle or thatch as a roof covering began to be employed by those who had the means of doing so. This, of course, tended to confine the ravages of fire to the building where it originated; but the houses thus erected were comparatively few in number, and it is to be remarked that in the decrees of the Assize of London, in the first year of Richard I.'s reign, no provision is made for chimneys. Richard's ordination says the walls were to be 3 ft. thick, 16 ft. high, and of hewn stone; upon these were built wooded gables of heights irregular, and instead of thatch they were to be slated or covered with Brent tiles.

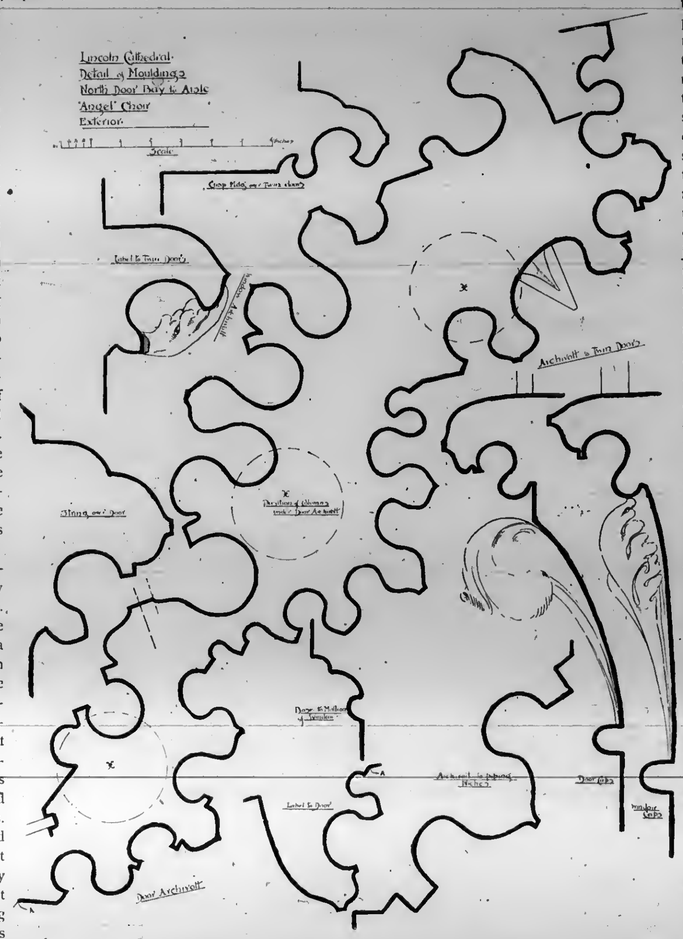
POINTERS ON TRADE JOURNALS.

It is a prominent and indisputable fact that those periodicals known as trade journals are great factors in individual business success at the present day. This is owing to their educational character and to the care and judgment exercised in their preparation. And while the field of trade journalism may be in many instances overcrowded, still there are few papers of this class which do not possess a peculiar merit that entitles them to consideration.

In the distribution of advertising patronage the importance of trade journals as mediums is too frequently overlooked, or else a proper value is not placed upon the quality of the publicity which they can give their patrons. Few general advertisers give thoughtful consideration to the claims which such papers present, and consequently fail to do justice to their worth; but indefatigable efforts on the part of the journals themselves must ere long bring to them the recognition they deserve. When an advertiser prepares to distribute his patronage there are three facts in connection with the different advertising mediums which he takes into account—quantity of circulation, quality of circulation and space rates. These then, are the facts to be considered in regard to the value of trade journals to advertisers.

First as regards quantity of circulation. It cannot be expected that a class publication will enjoy the same field favorable to the acquirement of enormous circulation figures that is accorded to newspapers. Being published for a class, it is of necessity confined to that class in securing readers, and its circulation is therefore limited to the magnitude of its class. But notwithstanding this fact, a study of the American Newspaper Directory will reveal a number of trade journals that possess a clientage surprisingly large, and there can be no doubt that the leading exponents of each line of business go to a very large percentage of the members of its own trade brotherhood.

But the shrewd advertiser well knows that the true merit of a medium does not lie in the size of its edition only. He looks deeper than this before investing in its pages, and it is here that the trade journal will bear the closest investigation and comparison. In the quality of its circulation, it possesses an unquestioned superiority over any other sort of publication. It fills a place that no newspaper or magazine can occupy, because it is of individual interest, while the latter is of general interest. It talks only about subjects that concern its class of readers, teaching them new business methods and the most profitable manner of applying these methods, so that it becomes a veritable schoolmaster in its own particular field. Thus by its educational facilities it contributes to the final success of many a struggling young business man, helping him over the rough places and guiding him to safer paths. It therefore follows that each issue of such a journal is regarded by its readers as a thing of value and carefully studied as a source of profit to themselves. It is preserved for future reference, and the advertisement it contains brings forth fruit long after those that have appeared in a newspaper are forgotten. I think it will be admitted that these valuable characteristics entitles the trade journal to a high position among advertising media. Now, a word about rates. It is true that class publications, as a rule, ask more for their space than newspapers, but take into consideration the quality of this space and then tell me if they do not deserve all they ask. Of course excellent judgment must be used in selecting the class of journals in which to advertise a certain kind of goods, but after this has been happily done compare the results with newspaper results in proportion to circulation. All articles cannot be profitably advertised in class journals, but many can be, and to advertise the latter I would rather pay five cents per line per thousand of circulation to trade papers than one-half to newspapers. Results will justify this assertion. — Jas. B. Kirk, in Printers' Ink.

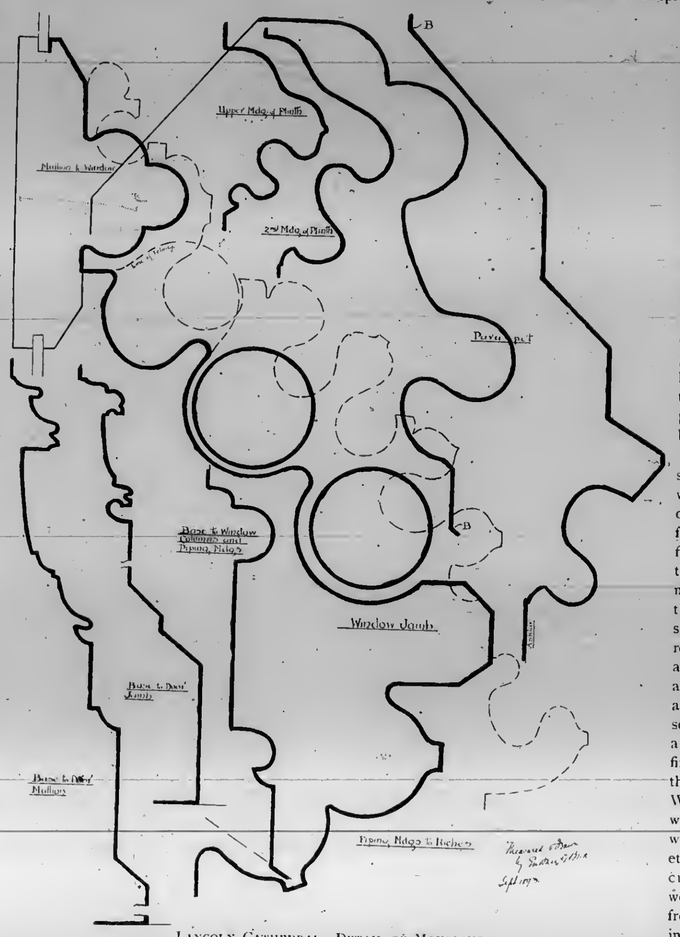


Whites from lead should never be used in water-color drawing. In many of the drawings by the old painters patches of black occur where the high lights were introduced. This is due to the use of white lead.

There has just come from the bending kiln of the Diamond Plate Glass Company, of Kokoma, Indiana, the largest bent plate glass ever made in America. The glass was cast and bent to order, and measures 108x133 inches, containing 100 square feet. The magnitude of this product can be appreciated when it is understood that in the two largest bending works in the country—the Oriel, of St. Louis, and the Trenton, of Trenton, N. J., no plate has ever been bent which contains over 35 square feet. The plate just completed will be used in a fine business building at Duluth.—Southern Manufacturer and Builder.

CONCRETE.

The discovery of the use of concrete is curious. In excavating for one of the piers of Waterloo Bridge, says the Builders' Reporter, the workmen had a good deal of difficulty, owing to the very compact state of the gravel forming the bed of the river, which everywhere else they had found perfectly loose. This effect had been produced by the accidental sinking of a barge-load of lime over that spot some time before, which had cemented the loose gravel into a solid mass, resembling the calcareous conglomerates of nature which are gradually formed by a similar process. Mr. Rennie having mentioned this circumstance to Sir Robert (then Mr.) Smirke, the latter with great judgment availed himself of the hint and subsequently used it in all his foundations, none of which have ever been known to fail. Part of the penitentiary at Milbank, begun by another architect in a different manner before Sir Robert Smirke was employed there, was evidently giving way. The superior efficiency of concrete was also proved in a remarkable manner at the new Custom House, where the floor of the large apartment called the Long Room actually fell in and the whole building was in danger, owing to the insufficient manner in which the piling had been originally executed in a very difficult situation. At this period Sir Robert Smirke was consulted, who found it necessary to pull down a small part of the building, but saved the rest of it by undersetting all the walls with concrete, to the average width of 12 feet and to the depth of from 12 feet to 15 feet—that is, until he found a natural bed of gravel, including one course of Yorkshire landing stones and twelve courses of brick laid in cement, having three offsets or footings between the Yorkshire landings, resting on the concrete and the base of the original walls. No other expedient could possibly have saved this fine edifice from entire demolition. It must be allowed that not only the ancient Romans and after them the Moors, but even the Norman barons of England in their feudal castles used concrete, of which Kendal Castle is one of the most striking examples; and more recently Belidor, in his "Architecture Hydraulique," treats of beton mortar, which is much the same; so that is not absolutely new. In fact, according to the old proverb there is scarcely anything new under the sun; but the merit of introducing this immense improvement systematically and generally into the modern practice of architecture is undoubtedly due to Sir Robert Smirke.



Lincoln Cathedral.—Detail of Mouldings.

PREVENTION OF FIRE.

A circular was recently issued by the Fire Underwriters of Missouri, under the above title. We quote here a few of the hints which will be found to be not only plausible, but eminently practical.

Electric trolley railroads should not be permitted to furnish light or power to any building, as it is highly dangerous, being almost certain to cause a fire in every instance.

Elevators, staircases, etc., should be in fireproof or fire-resisting shafts or in hallways, cut off from the main structure by brick walls, with self-closing doors at each storey, which latter would be improved if covered with metal on both sides. Where elevators and staircases are not cut off by brick walls, they may be cut off at small expense by metallic lath or plaster partitions of patent plaster blocks.

Ventilating shafts, dumb-waiters and all other openings from floor to floor throughout the buildings, if necessary (and they seldom are) should be of fire-resisting material throughout; at best they are are likely to serve as flues, and convey fires throughout the structure. Wooden-chutes, wooden dumb-waiter shafts, etc., are inexcusable, and well-holes, while frequently found in mercantile buildings, ought not to be allowed anywhere. Electric wires should be run through strong tubes of brass or other metal, with hard leather insulation. Where not so protected, the driving of a nail by some careless mechanic, breaking the insulation and cutting the wire or combustible material, may cause a short circuit and a serious fire. A small inexpensive fire-extinguisher kept on the premises may be the means of saving your property in case of fire.

PUBLICATIONS.

The Consolidated Plate Glass Co., of Toronto, have issued a perpetual calendar, handsomely mounted, with the company's name and address in silver letters on the front.

Just preceding the famous Charcot's death he prepared an article for The Cosmopolitan on Pasteur, to be published after Pasteur's death. But Charcot has died first, and so with the consent of Charcot's executors, the article is given now.

CANADIAN v. IMPORTED CEMENTS.

McGILL UNIVERSITY,
MONTREAL, Jan. 1st, 1895.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—I notice in your December issue, a somewhat lengthy criticism on an article written by myself, for the Canadian Engineer. I prefer, myself, to write over my own signature in criticising other articles, and, I am sure, if Mr. Wright had known that his name was to be dragged into the discussion, he would have preferred to have made his views known in a letter signed by himself. The Bystander, I presume, is a reporter or else someone interested in Canadian cements.

It is somewhat amusing to see myself put down as having English and Montreal sectional feeling, being as I am of Canadian stock for many generations back, born in Ontario not far from Toronto, and trying at every possible turn to do all I can, in my humble way, to make Canada greater and stronger. It is not necessary to state this to my friends, but as most of your readers have now heard of me for the first time I think this ought to be stated in justice to all concerned.

What has my critic proved? Nothing! I stated that the Canadian portland cements could be very good, and gave facts to prove it. I stated that they could also be found, at times, very poor, and gave facts there also! What has this on the face of it? Lack of patriotism? Is it to the true interests of an infant industry to lull it into the belief that it has reached a safe position?

If you will pardon a little more discussion, I will give you some incidents: A gentleman building sub-aqueous work asked me about a certain Canadian brand. I praised it highly, but explicitly stated that my samples had come from the manufacturer. I was then commissioned to test *it* and the Burham English brand. The Canadian one would have been taken if satisfactory, as the Burham, though a safe ordinary cement, is very coarse, having 5% residue on a 50 sieve. When I went to get the samples, at the dealer's, the Canadian cement I was shown for *competition*—far from being a good one—was simply vile. I protested, and urged the dealer to see if this was not an especially poor grinding. He obtained samples from another shipment, which I also tested. This also was too poor to consider at all—and thus the Canadian manufacturer lost a heavy sale—lost prestige. Why? Because, although he could turn out a very good cement, he also allowed very poor grindings to pass out of his own works (all marked with the same brand) to earn him a reputation. I have no doubt that many other experiences could be given by your readers of similar cases, whereas it is well known that the many years experience, large plants and careful chemical inspection have enabled English and other makers to turn out an article which, although not first-class, is yet not *variable*. A shipment of 4,000 bbls., if tested say every 100 bbls., could be depended on, while, if a Canadian maker who turns out 50 to 100 bbls. per day does not keep turning out the same article day by day, it will take the most exhaustive testing to detect the sudden variations.

What I advised was, increasing vigilance on the part of Canadian makers, that they might, by turning out a *uniformly* good article, gain the confidence of the army of consumers who do *not* test every 10 bbls; and, I repeat it, I see no better way than to have impartial tests made monthly, and published.

That, however, is a matter of judgment. As to the matter of facts, they stand uncontradicted. They were written with the best of intentions, and I believe will bear fruit. If, no other, they will call public attention to the industry, and warn the manufacturers of the pitfall. I explicitly stated in my article that I believed some makers were not in need of this criticism, and my best wish is that, in the near future, increased care, increased output and increased appreciation of that which is worthy, may put them all in the front ranks and put an end to importation.

Yours sincerely,
CECIL B. SMITH.

The CANADIAN CONTRACTORS' HAND-BOOK. Price $1.

THE ACCIDENT AT THE MONTREAL STREET RAILWAY COMPANY'S BUILDING.

MONTREAL, January 14th, 1895.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Amongst the correspondence in the last number of the CANADIAN ARCHITECT AND BUILDER, under the heading, "Montreal Street Railway Building Collapse," appears a report purporting to have been drawn up and signed by Mr. W. McLea Walbank, B.A.S., M.C.Soc.C.E., &c., and Mr. Lacroix, City Building Inspector.

It was commented upon in the following terms, namely: "That as there was much diversity of opinion amongst the experts examined, you would print only the conclusions arrived at by them; whose opinion as embodied in the report you should regard as being impartial."

It may perhaps be somewhat of a surprise to you, as it certainly has been to Mr. Lacroix and myself, to find his name attached to a report which, as he states in his letter to me, given below, he did not sign, and was no party to; and further, which arrives at conclusions he has not yet gone into or expressed any opinion upon.

What object was to be gained by tacking the City Building Inspector's name to the report, without his knowledge, is left for those doing so to explain, if possible.

[COPY OF THE INSPECTOR'S LETTER.]

OFFICE OF THE BUILDING INSPECTOR,
CITY HALL, MONTREAL, Dec. 24th, 1894.

EDWARD C. HOPKINS, ESQ., Architect.

DEAR SIR,—Your favor of the 22nd just received. In answer beg leave to say that I have not seen the article referred to in THE CANADIAN ARCHITECT AND BUILDER; furthermore, that I have never signed Mr. Walbank's report; besides I have yet to express an opinion as to the true cause of the collapse.

Yours truly,
(Signed) P. LACROIX, Building Inspector.

Trusting you will give this communication the same prominence which you have to Mr. Walbank's report,

I am, Sir, yours respectfully,
E. C. HOPKINS.

RECENT CANADIAN PATENTS.

No. 47,418, window sash, R. Heinrich Wilhelm Rump, Hamburg, Germany.

No. 48,434, process of making building blocks, Theodore Sanford Pierce and Fred. C. Norris, Lansing, Mich.

No. 47,446, Closet, W. B. Malcolm, Toronto.

No. 47,448, Brick mould, Carl F. Kaul, Madison, Neb.

No. 47,450, water closet flushing device, W. R. Baker, Watertown, N. Y.

No. 47,459, Sash fastener, Lewis Cass Miller, St. Louis, Mo.

No. 47,482, plate or pieces of glass having imbedded in it metallic wires covered with asbestos.

No. 47,503, a bath, consisting of an inner shell with a covering of pulp or papier mache, J. O. Thorne, Toronto.

No. 47,532, fastening for metallic roofs, John Osborn Pew, North Bloomfield, Ohio.

No. 47,541, window frame, Oscar Frostscher, Philadelphia, Pa.

No. 47,556, roofing tile, Thos. Arundel Aldridge, Bridgewater, Somerset, Eng.

There are many ways of frosting glass, some of the plans making the glass permanently frosted, others only temporarily so. For permanence, take a flat piece of marble, dip it into glass cutters' sharp sand, moistened with water; rub over the glass, dipping frequently in sand and water. If the frosting is required very fine, finish off with emery and water. As a temporary frosting for windows, mix together a strong, hot solution of Epsom salts and a clear solution of sulphate of soda, warm; and when cool, wash with gum water. Or dab the glass with a lump of glazier's putty, carefully and uniformly, until the surface is equally covered. This is an excellent imitation of ground glass, and is not disturbed by rain or damp.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

Negotiations have been in progress of late between the Brick and Stone Masons' sections of the Toronto Builders' Exchange and delegates from the unions representing the journeymen in these trades, as to what should be the rate of wages on the termination on the first of May of the agreement entered into by the employers and employees five years ago. The employers are understood to be averse to making a new agreement except the rate of wages be reduced to correspond in some measure to the universal depreciation in values. On the other hand they show no disposition to depreciate wages beyond this point. No understanding has yet been reached, but it is entirely probable that the matter will be amicably adjusted, either by the renewal of the agreement, it may be on different terms, or by mutually consenting to do without an agreement. There is no doubt that a satisfactory agreement would be the most advantageous settlement of the matter for all concerned.

THE Ontario Association of Architects has decided to hold an exhibition of architectural drawings in connection with the Royal Canadian Academy exhibition, which is to take place in Toronto next May. The Academy have very generously granted the Association the exclusive use of one of their rooms, which in point of light and location is equal to those allotted to paintings. Such a favorable opportunity of exhibiting their work was never presented to the architects of this province at least, and we trust they will not be slow to manifest their appreciation of it. A hanging committee, composed of members of the O. A. A., will be appointed, who will select from the drawings submitted those which by merit would be entitled to a place in the exhibition. No drawing which has previously been exhibited in Toronto wil be allowed a place in the exhibition. It is important to the success of the exhibition that the hanging committee should have in its composition sufficient back-bone to unhesitatingly reject without fear or favor such drawings as fall below the proper standard of merit. It is no less important that those submitting drawings should determine that they will cheerfully bow to the judgment, favorable or otherwise, which the committee shall pass on their work. If these points are strictly observed, we may expect that the approaching exhibition will be one which will be creditable and in every respect advantageous to the profession.

THE greater part of our space in the present number is given to a report of the proceedings of the recent annual convention of the Ontario Association of Architects. Notwithstanding that the number of pages has been increased, the space at our disposal is insufficient to present all the excellent papers read at the convention. Those which we are obliged to hold over will appear in our March number. In point of interest the convention was probably the most successful in the history of the Association. As regards the attendance, there is still ample room for improvement. Each year serves to emphasize the fact that there is a useful work for the Association to do, principally on the line of the education of future generations of architects. It is to be hoped that there will be manifest on the part of students of architecture a greater appreciation of the self-sacrificing efforts which are being put forth on their behalf by the older members of the profession in the Association. Instead of shirking the

examinations, because they do not happen to be of pulsory character, every student who hopes to succeed in profession should gladly present himself as a candidate for examination for the sake of the benefit which must accrue to himself from a thorough mastery of the examination subjects. It is to be hoped that the recommendation embodied in Mr. Gordon's resolution with regard to the Association Library, may be successfully carried out.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE monthly dinner and meeting of the Province of Quebec Association of Architects took place on Tuesday, the 15th January. Mr. A. T. Taylor, F. R. I. B. A., gave a very interesting lecture on "The Three Cathedrals of St. Pauls, London," accompanied by numerous sketches and drawings of the different structures that succeeded one another on the present site of the Cathedral. The present St. Paul's rests on the site previously occupied by two other churches; it is even claimed that on the same site was erected a temple to Diana. Very little is known of the Saxon church, which must have been of a primitive character, and built of perishable material as were most of the buildings of that agitated period. The structure that replaced the last named was well worthy of notice; it was in the gothic style and of a typical English character. Its spire was the highest in Europe at the time, and was rich in "souvenirs" and legends, and also contained in itself two parish churches, which had, strange to say, preserved its servitudes and priveleges. At about the period of the Reform it was used successively as a market and exchange and even as a stable. Later on Sir Christopher Wren, the architect of the present St. Paul's, was commissioned to repair the building, and added to its principal facade a porch in the Renaissance style of that period. The great fire of London put a stop to the restoration of the church. Sir Christopher Wren then prepared numerous drawings and schemes for the cathedral destined to replace it, but as often happens, the scheme recommended by the architect was not accepted, and Charles II adopted the plans of what he thought was a more ecclesiastical looking building, but leaving to the architect the liberty of altering and improving the original design. The architect took advantage of this latitude and produced one of the finest monuments in existence. This cathedral is the only building of any magnitude erected under one architect, the cross surmounting the dome having been set in position thirty-five years after the laying of the corner stone. Its dome is reputed the finest and best proportioned in the world.

A discussion took place after the lecture, and a vote of thanks was tendered to the lecturer for his interesting paper, proposed by Mr. J. E. Resther and seconded by Mr. J. Venne.

At the last monthly dinner of the Association held on the 12th instant an interesting lecture was also given by the Secretary, Mr. J. Venne, on "The Interior Management of the Architect's Office," and was discussed amongst others by Messrs. Jas. Nelson, A. Raza and J. E. Resther.

BRITISH COLUMBIA AFFAIRS.

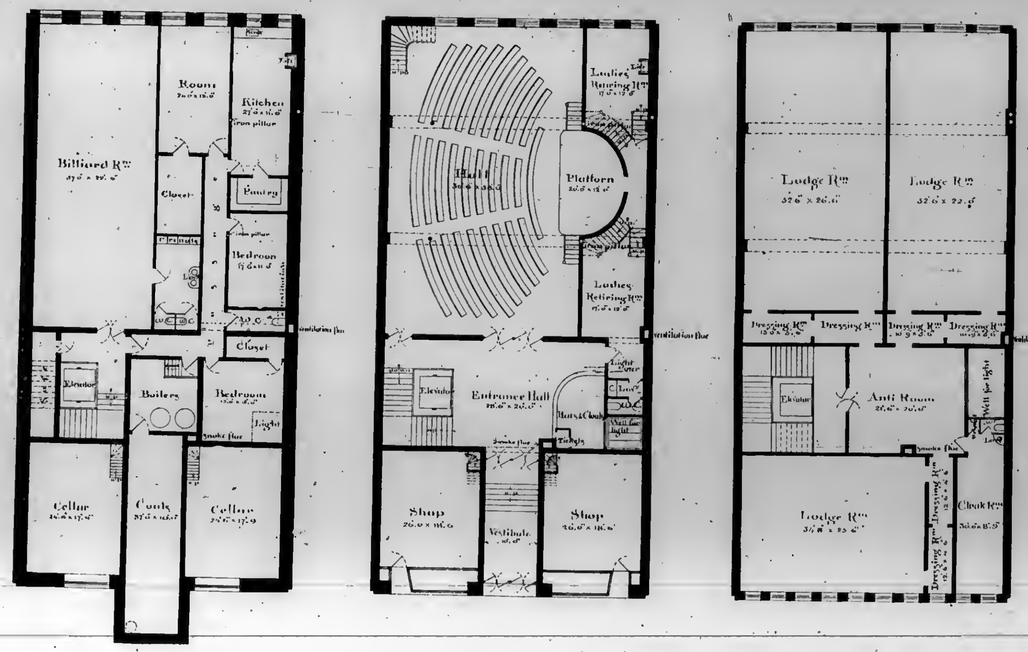
VANCOUVER, B. C., Jan. 29th, 1895.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—Please find enclosed P. O. order for renewal of my subscription to your journal, which in my opinion is making steady progress and becoming of more value to men in my line of business with each issue. I am much pleased with the current number, but notice several errors in your building notes from this city. Mr. N. Hoffar and not Mr. Fripp was the architect of the court house. Mr. Fripp was the architect of the "Inns of Court," a large office building costing about $30,000, which was built opposite the court house last year. Mr. N. Hoffar was also the architect of the Horne block (stores) $10,000. Another neat building built last year was the Garnbrinus Hotel, Mr. Thos. Hooper, of Victoria, B. C., architect This building was faced with pressed brick; cost $10,000. "O. Wick" is rather an obscure contraction for C. O. Wickenden, the name of the architect of the Hudson Bay Co.'s building.

An article on the rights and privileges of owners who wish to build basement buildings adjoining those which have none, would be appreciated here I think. I know of no law (local) governing such cases. This question should include another, that of putting outside footings on foundation walls which extend to the adjoining property. There has been no trouble that I am aware of on these points as yet, though there have been several cases which might have resulted in a law suit. We ourselves have had some narrow escapes. In one case we put a footing out on a lot adjoining the lot on which we built a building having no basement. This footing was about six inches over the line and the whole length of the lot, 120 feet. The owner, as many Vancouver owners do, resides in Europe I think. If you can give us some information about the laws and customs regulating these matters I am sure they will be much appreciated.

Yours respectfully, A. E. CARTER.



PLANS ACCOMPANYING COMPETITIVE DESIGN FOR MASONIC TEMPLE, MONTREAL.—J. R. RHIND, ARCHITECT.

ONTARIO ASSOCIATION OF ARCHITECTS

PROCEEDINGS OF THE FOURTH ANNUAL CONVENTION.

At 2 o'clock p.m. on Tuesday, January 15th, the President, Mr. Edmund Burke, called the Convention to order. The minutes of the last convention were read and approved. The President then delivered the following address:—

PRESIDENT'S ADDRESS.

GENTLEMEN: It is my pleasing duty to meet the members of the Ontario Association of Architects in this, the fifth annual convention since our incorporation. The year has been comparatively uneventful as far as our own history is concerned.

In response to the expressed wish of the convention, the Council inaugurated a system of lectures under the auspices of the Association. Two lectures have been given. The first, by Mr. Grant Helliwell, was open to the public, and was given in the hall of the School of Practical Science. It was a well prepared paper on "Current Architectural Styles," splendidly illustrated by Mr. Wright, of the School of Practical Science, with the aid of the fine lantern of the institution. The attendance, especially of members of the Association, was much less than the merits of the lecture deserved. The second lecture, given in the Canadian Institute by Mr. Wright, on "Graphic Statics," was a thoroughly good and practical exposition of the subject, and deserving of a much larger audience than was present—the total attendance, including lecturer and assistant, being only 18. Half of that number, only, were members of the Association, and the rest mainly students and draughtsmen. These facts are noted in view of the tendency to criticise the Council by some members of the Association who are prone to hint that this body is inactive and not alive to the interests of the Association. It is safe to assume that not one of these critics took the trouble to attend either of these meetings. Other critics have from time to time been invited to lend their aid to advance the interests of the Association, and have either refused or ignored the request. The members would do well to remember that their attendance at the meetings would not only be of benefit to themselves, but an encouragement to the gentlemen who, at much expense of time and thought, have prepared papers. The interchange of thought in the after discussions on the subjects presented, may be made most interesting, especially when the attendance is large—numbers always adding to enthusiasm and interest. It is an encouragement, however, to those who so kindly prepare papers for the enlightenment of others, to discover, as so many have by experience, that, while adding to the information of others, the knowledge they impart becomes doubly their own.

An event of decided interest, and having possibly an indirect bearing on the future of the Association, was the election of a new legislature for the province, a few months since. Your Council seized the occasion to endeavor to enlist the members of the Association in an effort to obtain an expression of the views of the various candidates with regard to the proposed change in our act. Our efforts were very poorly received, few of our men reporting any action in the premises.

Now that a new House has been elected, it is of the utmost importance that every member be up and doing from this time on. If each man would make a point of seeing his representative, of urging upon him our claims and explaining fully our position and aim, the chances of success in the next session of the legislature would be greatly improved. Leading men on both sides of the House have expressed themselves as favorable to our cause and have assured us of their support, at the same time warning us that we must work hard to secure the support of a large number of the rank and file, if we would look for success.

We were advised, as was stated in the address of our President at the last convention, that the temper of the House in its closing session was not favorable to the increase of close corporations. As we unfortunately were in the company of other organizations seeking, for them, unusual powers, discretion seemed to be advisable, and we withdrew our bill. Such may have to be our course again, and as the composition of the House has been considerably altered, no forecast of the situation is possible. But even if we do fail in our object at the coming session, we must not be discouraged, but hope on. We believe our cause is just and right, and that not only ourselves but the public will share, in days to come, in the benefits that will accrue to the profession in the elevation of the standard of education and professional training which will assuredly follow the legislation sought. We must, therefore, not swerve from our goal though it take years to reach it.

Education must ever be our watchword; the higher we reach in professional attainments and knowledge, the farther away will we get from charlatanism and unprofessional conduct, and the nearer will we approach the highest type of professional ethics. The question of education means for the older men considerable self-sacrifice; for the examiners much time and trouble; for the principals, the yielding to their students of considerable time for study and examinations, and the prospect of raising up competitors, who in years to come, by reason of their better preparation, will outstrip their masters in the race for employment. But what of this? Shall the profession stand still that the older men may not be outstripped? This would indeed be a low platform for men aspiring to be artists and the leaders of artistic thought in the community. The coming Canadian architect needs a better education for another and more sordid reason, but a very present one nevertheless, and one which we have very severely felt in this country of late years, namely—the competition of foreign architects. Some of our most expensive buildings have been erected from the designs of aliens. The apology for this is the alleged want of experience and ability on the part of the native architect. We do not admit for one moment the validity of this contention, the fine buildings erected by local men attesting to the contrary; but that this is, to a considerable extent, the condition of affairs is a well known fact. This contention is not advanced with regard to the employment of other professions in Canada, because they have aimed at and attained a high standard of professional education. The lesson for us is evident.

We need also an education, or lifting up, in the matter of professional ethics. Too often an architect is confronted with the competition of two or three of his fellows in a case where he supposed he had a client. He submits a sketch, perhaps without a definite engagement, talks it over with his client and leaves the matter with him for a few days' consideration. On his next visit he is confronted with the information that Mr. So-and-So has submitted a sketch (a catchy, showy one), probably backed up with the assertion that the design can be executed for 30 or 40% less than his, and at a commission far below the regular fee. There is little use in telling the client that your rival is not speaking the truth. The aforesaid rival has offered to guarantee the cost, and the client does not see why he should pay so much more for his building to oblige you. You are accordingly allowed to depart without a commission, meeting, perhaps, one or two more hungry applicants on your way out. It is small satisfaction to be informed, after the building has been erected, that your rival has run his client into an expenditure far greater than your estimate.

Good men are sometimes drawn into this unseemly form of competition from the fact that they do not feel like being ousted in such a manner—losing work which to all intents and purposes is theirs. And what is, what only can be, the inference drawn by the client? Simply that architects are a parcel of fools, and that he can use them as tools, one against the other, and thus dictate his own terms.

I speak thus plainly, because I notice a growing tendency along this line since the advent of an Ishmaelitish element into the craft a few years since. The other professions are an example to us. Physicians and lawyers observe their codes of ethics; they set their standard high and are rated by the public accordingly. When will we be wise enough to learn the lesson? Closer association and more intimate acquaintance with each other has helped us greatly; but ever and anon are some found who resort to the original type when assailed by the temptation of a possible commission. It is a pity that men, especially young and clever ones, should descend, even for the sake of obtaining work, to anything in the shape of unprofessional conduct. In an experience of 25 years, I have found that none have succeeded permanently and obtained a good name in the community who have endeavored to build their success at the expense of their professional brethren.

No competitions of importance have been inaugurated in the province this year. The few small ones, notably the London Free Library, have been unsatisfactory in results, as usual, the two chief reasons being the lack of proper judges and the absence of a properly prepared programme of requirements. Both these necessary accompaniments of a well conducted competition are embodied in the form suggested by the Council and approved by the Association, and it rests entirely with the architects themselves as to whether satisfactory methods of competition be insisted upon. The remedy is in our hands. Are we going to be always so miserably selfish as to ignore proper methods in ridiculous scrambles for the opportunity to obtain a commission?

The question of an exhibition of drawings in connection with our annual meeting was broached a few weeks since, but it was felt that the time was too short in which to assemble a representative collection. Possibly a mid-year exhibition would be practical and popular, and while keeping up an interest in the Association would avoid a possible clashing with the business of the convention.

Our sister Association in the Province of Quebec has not been idle during the year. A reading room for members and students has been opened, classes for students organized and examinations conducted. A very successful exhibition of drawings was organized in connection with the annual meeting last October. It had the advantage of being held in the galleries of the Montreal Art Association and drew a fair attendance. A considerable number of drawings was sent by members of the Ontario Association, under arrangements for transport made by our Registrar.

The Quebec Association has followed up the suggestions of Mr. A. T. Taylor, who read a paper at the annual meeting, advocating an Advisory Art Committee, by passing a resolution proposing to the City Council of Montreal the appointment of such a committee, consisting of artists, architects and others to supervise the erection of public monuments and the laying out of public parks, squares, etc. A league having similar objects in view is being formed in Chicago, while Boston and New York have their municipal art societies. Other cities and towns in Canada should join in a similar movement. Monuments are being located and erected without that thought and supervision which would add greatly to their character and effect; and committees and officials often take upon themselves responsibilities for which they are unfitted, not through any fault of their own, but simply for lack of education and taste in such matters.

The architectural department of the School of Practical Science is making considerable progress and appears to have developed as fast as the funds at disposal will permit. The period of study embraces a course of 3 years with a 4th or post graduate course. An expansion of the course, however, is a prime necessity if this department is to be fully and properly developed. If this is not done, there is a danger that the architectural schools in the United States will attract many of our young men, who can afford the additional expense, by reason of the more complete courses of study afforded, including training in design, a most necessary phase of an architectural student's education. The architectural library of the school is growing by judicious purchases including valuable photos of ancient and modern buildings. Having begun the work it behooves the Ontario Government to as wisely forward the development of this department as it has that of the engineering department. Failing this, much that has already been done will fail of its expected result.

In connection with the School of Science, I would here refer to the series of tests which have been made during the past year in the institution by Mr. Wright with our local Portland cement. This industry has witnessed a remarkable development during the past decade which is an evidence of the increasing demand for more enduring methods of street paving and better building construction.

The Toronto Technical School conducting evening classes is an institution which is doing a considerable service for Toronto architectural students in helping to prepare them in mathematics for the Ontario Association of Architects examinations. Eleven architectural students and ten draughtsmen were in attendance at the classes of 1893-94.

The three chief architectural bodies in the mother land appear, from their reports, to have been actively engaged during the past year. The Royal Institute of British Architects in November last inaugurated a system of progressive examinations, which have succeeded the former and partly tentative arrangement. The President, Mr. F. C. Penrose, F. R. S., in a late address considered that these examinations "could not but have an excellent effect; first and directly in securing to future members of the Institute the reputation of having satisfied a certain standard of proficiency; secondly and indirectly, by excluding from the Institute in the first instance and by reaction from the profession at large, young men whose abilities would have been more advantageously directed towards the pursuit of some other calling." Some conception of the work of the Institute and the number of architectural students may be found from the following figures, viz: In the preliminary examinations 165 students attended, 28 were conditioned and 136 passed. In the intermediate 55 attended, 19 were conditioned and 36 passed, while in the qualifying or final examinations 150 attended, 84 were conditioned and 63 passed. The Journal of the Royal Institute forms a quarterly volume of exceeding value and interest, many of the papers being profusely illustrated.

The Architectural Association appears to be a model institution, and doing good work in the matter of architectural education. Its classes are divided into two groups—the lecture and the studio side—with courses or years divided into four divisions, with examinations, medals and certificates in each. In addition there are valuable prizes as follows: Architectural association medal with a prize of the value of 10 guineas; measured drawing prize; essay prize, value 10 guineas, and silver medal; Cates scholarship tenable for two years; travelling studentship with bronze medal and the Oliver prize. These prizes were awarded at the opening of the session, and the President, Mr. Mountford, F. R. I. B. A., in stating that the past session had been the most successful one under the present order of things, announced that of the 96 new members who joined their ranks last session no less than 73 joined either the classes or studio, while 78 students took up complete courses of lectures and classes.

The third of the Associations referred to—the Society of Architects—is also a flourishing institution, with over 500 members and associates on the roll. The Society is ten years old and has been incorporated one year. It supports a journal which includes in its columns the proceedings of the Society, architectural notes and queries, notes on new books, etc. A somewhat unique feature of this Society is the periodical visits of the secretaries to the members residing in various provincial towns. It is also in contemplation to hold meetings in large provincial centres if the members in those districts indicate a substantial interest in the scheme. The Society has decided that after Oct., 1896, election to membership will only be open to candidates who have passed certain prescribed examinations, making exceptions however in favor of applicants over the age of 35 and who have practised for seven years. The adoption of this scheme by the third great architectural body has given rise to some dissension regarding the question of confining the examinations to a sole examining body, one of the past presidents maintaining that all examinations ought to be in the hands of the older and representative body, the R. I. B. A.

The R. I. B. A. is named in the registration bill as the sole examining body, the promoters belonging to various architectural societies having made this concession to the Institute. The Institute, however, persists in opposing the bill, taking the high ground that the members of a great profession should carry on their work in a manner perfectly free from the trammels of legislation. The R. I. B. A. at the same time admits that its provincial members, especially, are subject to the "depredations of unprincipal quacks." The only remedy suggested by the Institute is, that the provincial newspapers be used in disseminating the fact that the members of the Institute have signed a declaration that they will not accept illicit, or surreptituous commissions, and that they will be bound by the rules of the Institute. It is to be feared that it will take a great many years to educate the public by this means. Legislation has not curtailed the usefulness of the legal and medical societies, neither should it that of the architectural, and the quackery complained of would soon be a thing of the past were it obtained.

The various architectural societies in the provinces of the United Kingdom are being affiliated with the Royal Institute, under the name of Allied Societies, with centres in the various large cities, thus very greatly extending the influence of the Institute and the prestige of the profession.

The 28th annual convention of the American Institute of Architects was held in New York in October last. The membership of 475 Fellows was reported the same as the preceding year, the increase having exactly equalled the falling off. The chapters of the Institute number 26, with an aggregate membership of about 600. A most important amendment to the by-laws was passed. By this amendment, an architect, in order to become a member of the Institute must first join one of its chapters, and every practising member of a chapter must become a member of the Institute. There is quite a possibility of friction arising out of this state of affairs, as some of the local bodies, notably the Boston chapter, have a greater voting strength outside than inside the membership of the institute. The two most important reports presented at the convention were, that on Education through Mr. H. Van Brunt, and on Competitions through Mr. Geo. B. Post. The report on education is a notable production of literary merit, and will repay a careful perusal, as it advances several good suggestions regarding the present phases and necessities of a proper architectural education. An important measure in the interests of architecture is now before Congress. It is known as the McKaig bill, and deals with the much vexed question of the preparation of designs for the government buildings. Under it a commission is to be appointed by the President, consisting of a board of two government engineers and three architects of high attainment and large practical experience. This Board is, in the case of buildings costing less than $100,000, to select an architect without competition, employing him to prepare the designs, working drawings and specifications. In the case of buildings costing more than the above amount, the Board is to inaugurate a limited competition, selecting at least five firms, and all competitors to be paid at the rate of one-tenth of 1% on the estimated cost of the building. It is fully expected that the inauguration of this departure from the present method will mark the commencement of a new and brilliant era in the character of government buildings in the United States.

It will be seen from these brief outlines that the English speaking societies of the architectural world are making the education of architects their chief business. The British societies are all looking towards an educational test for membership; they, with the strength gained through numbers, are conducting classes with progressive and systematic studies and examinations which are yearly becoming more exacting. In addition to the work of the societies, most of the large centres have the advantage of splendidly equipped technical schools, many of which have special classes for preparing students for the examinations of the architectural societies. The University of London is also abreast of the times, having a chair of architecture ably filled by Mr. T. Roger Smith. Our association is to some extent following the lines of the English societies in regard to examinations, preliminary, intermediate and final, the latter admitting to membership; but, so far, through lack of means and strength, without the establishment of classes. The Americans, on the other hand, have, so far, instituted no examinations for admission to membership, and have not, through their chapters or institute, organized any system of classwork. The development of architectural departments in many of the United States colleges, however, has been very marked, largely taking the place of the English methods, and in some of them the courses of study have become very thorough, the influence of the Paris school being predominant. This, with the return of American students from the Paris Ecole de Beaux Arts, has greatly stimulated the spread on this continent of that phase of Renaissance architecture which has long been the fashion in Europe and which bore such abundant fruit in the buildings of the great Fair at Chicago. A Society of Beaux Arts has been organized in New York, composed of men who have studied in the Paris school. The primary object of this society is to preserve among its members the traditions of the French school and to propagate its methods in the United States and thus educate the younger men in the profession along its lines. Quarterly competitions have been established, conducted similarly to those in Paris, and open to all students of architecture. Several of the members have opened ateliers and conduct them on similar models to those of the patrons in Paris.

But from the expresssions sent forth by the leaders of architectural thought, there is an evident movement towards a more thoughtful and appropriate treatment of the architectural problems of to-day. They are depreciating the selection and slavish copying of certain historic styles, and yet insisting that the study of all the historic styles should be systematized and co-ordinated, not, as Mr. Van Brunt says, "with the minute patient scrutiny of the archaeologist; but with the spirit of the artist seeking to learn how forms and ornament were developed out of the genius of civilizations and peoples and how, as they were significant of the progress of human culture in the past, they should be used in the service of modern art."

The need of our architectural era is therefore without doubt such education in design as will enable us to make architecture as a fine art keep pace with science. In the mediaeval times the scientific practical constructor and the artist were one person; in our times they are practically two. Must we not at least learn how to unite the two into one with our new problems and new materials? Engineering needs to be converted into architecture and the architecture of the near future must therefore be made to conform to this new character. Practitioners, engrossed with the details of business are too busy to solve these problems or to enter into the study necessary to satisfactorily solve them without a long process of evolution, with many hideous examples and failures on the way, as we are witnessing in the high structures of to-day. The schools then must needs help us with, to again quote Mr. Van Brunt, "a much more scientific co-ordination of precedent, a much more philosophic analysis of the architecture of the past than is secured by our present methods of education."

I must not close without reference to the severe visitation of fires which has caused such a stir and comment in Toronto during the past few days. Advantage should be taken of the occurrence by all architects to inculcate and advocate the necessity of erecting a more solid class of structure in the business districts. It may not be possible to accomplish this with clients who are anxious to erect the largest buildings for the least money; but we can at least lend our aid to the enactment of more stringent building laws and the enforcement of closer and more intelligent inspection of buildings under course of erection. It seems to me that the chief lessons to be learned from an examination of the burned structures are:—The necessity of thick walls, including party walls; the resting of wooden joists wherever practicable, on corbelling, instead of the ends being built into the wall; the necessity of fire-proof shutters on all openings which are exposed to risk of fire from adjacent premises; the unreliability of steel unless thoroughly protected from even a moderate degree of heat, and the necessity of fire-proofing all business premises which exceed a height of about seventy feet.

And now I will not detain you farther from the business for which you have met than to say, that I hope we may enjoy our annual reunion; that the papers and addresses may be as beneficial to the hearers as they have doubtless already proved to those who have so kindly prepared them; that our criticisms and remarks may be uttered in the spirit of frank brotherly kindness, that the occasion may be one of refreshing to us all, and that we shall be encouraged to enter upon another year with fresh impulses towards the highest development of our powers in our noble calling, and with a firm resolve to observe the golden rule in all our dealings with one another.

TREASURER'S REPORT.

The Treasurer, Mr. H. B. Gordon, then read his report as follows:

THE TREASURER IN ACCOUNT WITH THE ONTARIO ASSOCIATION OF ARCHITECTS.

Dr.

1894.			
Jan. 1	To balance from 1893		$1,930 50
Dec. 31	Members' Annual Fees		217 00

Balance	2,483 80
	$2,608 00

On motion by Mr. M. B. Aylsworth, the Treasurer's report as adopted.

REPORT OF REGISTRAR AND LIBRARIAN.

Mr. W. A. Langton, Registrar, then read the following report:

REPORT OF THE REGISTRAR AND LIBRARIAN AT THE ANNUAL MEETING ON JANUARY 15, 1895.

Members.

The following is the state of the roll of membership of the Association:—

Membership on December 31st, 1893—	
Resident Members	65
Non-resident	70
Residing out of the Province	4
Total	— 139

The names of four resident members who had left the country were omitted from the printed register of 1894. One resident member subsequently resigned and a non-resident member died. There were three resident members registered in 1894; and one member residing out of the Province. The roll of membership on Dec. 31st, 1894, therefore, was as follows:—

Resident members	63
Non-resident	69
Residing out of the Province	5
Total	— 137

The status of members with regard to the annual fee is as follows:

In good standing	35
Honorary	1
In arrears for 1894	49
" " and 1893	31
" " " and 1892	12
" " " " and 1891	9
	— 137

The classification of members with regard to the grading of fees, and the amounts of fees due and paid, are as follows:—

CLASSES.	No.	Fee.	Amount Due.	No. P'd.	Amount Paid.
I.—Practising in York County, 5 years and over	53	$5.00	$265.00	9	$45.00
II.—Practising in York County, under 5 years	4	3.00	12.00	4	12.00
III.—Practising in cities outside of York, 5 years and over	34	3.00	102.00	7	21.00
IV.—Practising in cities outside of York, under 5 years	2	2.00	4.00	2	4.00
V.—Practising in towns, villages, etc	23	2 00	46.00	4	8.00
VI.—Civil servants	13	2.00	26 00	4	8.00
VII.—Not practising in Ontario	7	2.00	14.00	3	6.00
Honorary	1	.....	.....	...	.....
	137		$469 00		$104.00

NOTE.—The number of members in Classes II. and IV. is variable, and is established by application for the rebate by those who are entitled to it when paying their fees. In the above list the number fixed for these classes is the number of those who have paid the reduced fee in 1895.

Of fees overdue at the end of 1893 there have been $113.00 paid during 1894, making the total payments of fees from members during the year $217.00. There have also been four new registrations and one registration fee of last year, which comes into this year's accounts.

Students.

Seven new students were registered during the year. There are now 92 students on the list, but of this number there are less than 50 with whom I can feel reasonably sure that I am in actual communication. Some are not in the country; some are, I think, engaged in other work; some I hear of as practising, having abandoned or postponed the idea of registration. But their indentures are still with me, and I have received from them no notice of their withdrawal from the Association.

Classified according to the examination required of them, the roll of students is subdivided as follows:—

For first intermediate examination	14
For second " "	27
For final examination	51
	— 92

Of the 51 students who must pass the final examination before registering there are 45 who have served their time.

The members of the Board of Examiners are:—Professor Galbraith, Principal of the School of Practical Science Chairman; Mr. C. H. C. Wright, Lecturer in Architecture of the School of Practical Science, Examiner in Mathematics, Graphic Statics, Strength of Materials, Nature and Propety of Building Materials; Mr. Edmund Burke, M.O.A.A., Examiner in Design; Mr. R. W. Gambier Bousfield, M.O.A.A., Examiner in the History of Architecture, Technical Terms and Architectural Jurisprudence; Mr. S. G. Curry, M.O.A.A., Examiner in Foundations, Heating and Ventilation and Sanitary Science; Mr. Frank Darling, M.O.A.A., Examiner in Design; Mr. S. H. Townsend, M.O.A.A., Examiner in Elements of Construction, Structural Iron Work, Practical Knowledge of Building Trades and in Design.

There were 13 students examined this year, with results as follows:—

	No.	Passed at first exam.	Passed at supplemental exam.	Plucked.
First intermediate	8	4	2	2
Second intermediate	2	1	1	..
Final	3	2	..	1

There is no supplemental examination granted to candidates who fail in the final examination.

Proceedings of the Council.

The Council, in order to keep down the running expenses of the Association, met only on the day after the Convention (Jan. 18), and on the morning of the present Convention.

In fulfilment of the instruction from the Convention to consider the advisability of calling an occasional meeting in Toronto of members of the Association, or of encouraging the formation of a local branch, it was decided to have two lectures in the course of the year, one to be of interest to the public, and one of a more technical nature for members. The first lecture was given on March 8, at the School of Practical Science, by Mr. Helliwell. The lecture was an expansion of his paper on Current Architectural Styles read at the Convention, and was illustrated by Mr. Wright by a large number of carefully selected views of buildings thrown on a screen by means of the magic lantern. The second lecture was on Graphic Statics, and was given by Mr. Wright on November 16, at the Canadian Institute.

An application was received from the Royal Military College Club requesting that graduates of the Royal Military College be placed on an equal footing with graduates of the School of Practical Science, with reference to the requirements of the Association from its students. The question arose whether the Association has the power to grant such a concession. The matter was referred to the Minister of Education, who decided that it was not within the power of the Association to so enlarge the scope of the Ont. Architects' Act. The Minister expressed himself in favor of granting the concession if found warrantable, and undertook to investigate the character of the work done in the architectural course at the Royal Military College.

Renewed efforts were made during the year to press upon the attention of the Dominion Government the need of an exact method of collecting the customs on foreign plans. Copies of the memorial presented to the Minister of Customs by a deputation from the Association in 1892 were presented again by Members of Parliament representing Toronto. The Controller of Customs replied that the system proposed in the memorial was already in operation.

The Library.

There have been no books added to the Library this year.

The number of lendings was 111, or 41 less than in 1893.

All of which is respectfully submitted.

W. A. LANGTON, Registrar and Librarian.

Mr. Billings took exception to the sense in which the terms "Resident Members" and "Non-Resident Members" were used in the report. He thought the Association being a Provincial one, that all members residing within the Province should be termed resident members, and not only those living in the City of Toronto and the County of York.

Mr. Townsend said the use of the word in that way was merely an error, which had no doubt occurred in the endeavor to distinguish between members residing within the City of Toronto and the County of York and those living elsewhere in the Province. He felt sure there was no intention on the part of the Toronto members to regard themselves as the only resident members.

The Registrar stated that the term referred to had been used in the by-law governing the classification of members, which was passed by the Council, and had in that way come into use, but he never made use of it in sending out notices in regard to the payment of fees, &c., without feeling its inappropriateness.

The President said he had no doubt if it was felt by the meeting that a change in this particular was desirable, the Council would willingly make it.

On motion by Mr. Aylsworth, seconded by Mr. Gibson, the report was adopted.

Mr. Paull expressed his appreciation of the comprehensiveness and instructive character of the President's address, and desired to call attention to some points referred to in it which he considered of great importance. One of these was the allusion to what was being done in Montreal in the appointment of a committee to look after monuments, &c., and to impart a more aesthetic spirit to the way in which such works were designed and carried out. Such a committee of architects, he thought, would be of great advantage to Toronto in the way of inducing authorities, where opportunity offered, to widen our streets and give open spaces such as were found in Detroit and other American cities. The President had also referred to the London competition. It was understood that in that competition there had been very considerable variation from the instructions issued, and he thought it would be well if the Ontario architects would take the practice of English architects as their example in that respect.

In a competition for civic buildings in Birmingham, England, some twenty years ago, the umpire, Mr. Waterhouse, declined to give the award to the plan which he thought had most merit simply because it departed from the instructions in the fact that a bridge not called for by them connected the public buildings and the new hall. A different system from that prevailing here was adopted in England regarding the premium given competing architects. In the case of the law offices they offered a premium of £1,000 to each of ten or twelve architects for their plans, and paid the one whose design was chosen, five per cent.

Mr. Tully said that before the discussion closed he desired to refer to the recent fires that had taken place in Toronto. He thought the civic authorities had made themselves subject to adverse criticism by the changes made in the fire by-law regarding the thickness of walls. After the great fire of 1849 the corporation asked the architects of the city to frame a by-law and he had been one of the architects on that occasion. After a full discussion of the matter, extending over a month, a by-law was framed by the architects and adopted by the Council, and remained in operation for a few years, but through the pressure brought to bear by speculative builders and others interested in putting up inexpensive buildings, this by-law was eventually amended, and had been at different times since amended in a way not at all in the public interest. Had the by-law framed by the architects remained in force he had no doubt much loss would have been saved to both owners of buildings and insurance companies. He thought it would be well before the convention adjourned to adopt a resolution calling attention to these facts, and offering, if the Corporation would refer the matter to the Association, to frame a new by-law, or suitably revise the existing by-law regarding building and fire limits in such a way as would prevent a recurrence of the late calamities. He thought such an offer would convince the citizens that the Association had their interest at heart, and if a proper by-law was framed it might be adopted not only in Toronto, but in other cities in the Province, and thus decrease the loss by fire now sustained by the community. He was much pleased with the manner in which the matter was alluded to in the President's address.

Mr. Gordon said that the matter had been alluded to at the meeting of the Council in the morning, and before the convention adjourned a resolution very much along the lines suggested would be submitted.

The President remarked upon the great pleasure he, and he was sure all the members, felt in having among them to-day Mr. Tully. When Mr. Tully referred to the year 1849, most of the members would realize that that was before they were born. In regard to the proposed revision of the fire by-law, he would say that two or three years ago the Toronto Architectural Guild was asked to appoint a couple of members to co-operate with a commitee from the City Council in regard to that matter. The work of the committee, however, was so intermittent, and the gentlemen from the Council appeared to know so much more of the subject than the architects, that many of the suggestions made were ignored, and the architects never saw the revised by-law until it was printed, and therefore could not in any way be held responsible for the inadequacy of the present regulations. It was the intention of the Council of the Association that the matter should be brought to the attention of the Mayor and Council.

Mr. Tully did not think the Association should consent to act in conjunction with persons not professional men in this matter. The City Council should refer the whole matter to the Association, who would draw up an amended by-law and send it on to the City Council as what they recommended. If that body then chose to amend the by-law the responsibility would rest upon them. He thought it would be most objectionable for the members of the Association to be placed on a committee of laymen, with whom they would have to wrangle in regard to the matter. He felt sure the public at large would support the architects in any by-law they would frame.

Mr. Paull thought the matter was one of the highest importance, and that it was imperative that some such action as that proposed by Mr. Tully should be taken, and he had prepared a memorandum dealing with the subject which he would read. "The recent experiences in this city in regard to the large fires; the great loss of property by owners; the great loss by insurance companies; the great and providential escape by the falling of snow from even greater calamities—but for snow we might have had a similiar experience to Chicago and Boston. Now a very important question arises, what is to be done for future protection against fire in Toronto? The answer to this question is a problem worthy of solution by the architects of the Ontario Association. No doubt with proper precaution and watchfulness much danger may be avoided. Outside of the buildings themselves there exist some means of salvation, as for instance, the procuring by the City Corporation of suitable and effective steam fire engines; the substitution of larger mains than those now in use, as recommended by Mr. Keating, the City Engineer. More care should be taken by the fire insurance agents themselves; more watchfulness by selected nightwatchmen, by the warehouse men and others of Toronto. But the erection of the buildings themselves is what more immediately concerns the architectural profession, so as to have all the available safeguards that can be possibly and prudently introduced during the erection of such buildings for the best protection against fire.

"First, as great care as possible to be taken by isolation from the surrounding buildings either in space or by effective outside walls.

"Second, the introduction by the Corporation of Toronto of the London (England) Building Acts as to brick walls and other building appliances now in operation in the largest city in the world.

"Third, great care in the selection, as far as possible, of indestructible materials, and such as will stand the action of great heat and steam.

"Fourth, greater introduction of hydrants into any newly erected buildings.

"Fifth, careful general supervision.

"Sixth, special care in the heating and ventilation.

"Seventh, introduction of new methods by the architectural profession, such as automatic apparatus, &c."

Mr. Tully, while agreeing that Mr. Paull's remarks were practical, considered that in any action it might take, the Association should confine its attention strictly to buildings. As an engineer he had his own opinion on the question of water mains, and he thought that defective methods in introducing electricity into buildings was a source of danger, and might possibly have been the cause of the recent fires, but these were matters which should be dealt with by the engineers and electricians. He did not think the insurance companies appointed proper surveyors when insuring buildings, many of them being men having no knowledge of architecture, and he could not believe that any man without that knowledge or a practical knowledge of the value of material could make an accurate estimate.

NEW BUSINESS.

The President invited the Association to consider the suggestion thrown out in his address in regard to an exhibition of architectural drawings annually.

Mr. H. B. Gordon, in order to bring the matter before the Association, moved "that it be a recommendation to the incoming Council that it is desirable to have an exhibition of architectural drawings held in Toronto at the time of the Industrial Fair, or about that time, when cheap railway fares would be an inducement to outside members to come in."

Mr. Harper seconded Mr. Gordon's resolution.

Mr. Billings (Ottawa) called attention to the fact that such an exhibition was a feature of the meetings of the Royal Academy. Though poor, so far as numbers were concerned, the exhibit was good in quality.

The Registrar suggested the holding of the exhibition in connection with the annual exhibition of the Royal Canadian Academy.

Mr. Billings approved of the suggestion, the more so that the Canadian Academy, like the Association, was "a struggling industry."

Mr. Gordon expressed his willingness to so amend his motion that the exhibition could be held at the time of the Canadian Academy's exhibition.

The motion as amended was then carried.

The Registrar said that, beginning at Chicago, and taken up

in Montreal and Quebec, a movement was on foot for the formation of societies to have the supervision of the ornamentation and laying out of those cities. He thought the Association ought to keep this in view, and inaugurate some similar action in Toronto. It might be some time before such an association was thoroughly recognized by the city, but he moved that the Council of the Association be instructed either to communicate with the City Council, with a view to establishing, if possible, such an association, or to consider how best to form such an association as would be recognized by the City Council.

Mr. Townsend, in seconding the motion, said he considered it a matter of very great importance that some standard of good taste should be established in connection with the matters referred to, and he could see no other way of establishing it than by the formation of such a body as suggested.

Mr. Paull agreed as to the importance of the suggested step, and instanced the proposed utilization of the Old Upper Canada College grounds as a hotel site as a matter in which such a society might find something to do. There was no site in the city better adapted for making a display worthy of it, similar to the Champs Elysee in Paris. The tendency in Toronto seemed to be towards covering every open spot of ground with buildings. If the promoters of the hotel project, instead of putting the hotel in the east end, would contribute $100,000 more and place the hotel in the centre of the block, there would be room for ornamentation. Unless something was done very shortly this opportunity would be lost.

Mr. Gregg thought that too much was being put into the hands of the Council, and that the present matter was one in which the Association as a whole was interested. Would it not be well to leave it in the hands of a committee of the Association residing in Toronto?

The President suggested that there were other places besides Toronto in which such action as was proposed might be desirable. A committee might be formed, representing all the cities of the Province, who would be in close touch with each other. He thought that a pronouncement on this subject coming from the Association would have much weight, and there was no reason why the movement should be restricted to Toronto.

Mr. Townsend was of the opinion that a representation coming from the Association as a whole would carry more weight than one from a local committee.

Mr. Aylsworth favored Mr. Gregg's view, because the Council met so seldom that it had little time in which to deal with such matters, and the Council did not seem to be very well known to the public. Instead of attempting anything so ambitious as the plan in connection with the hotel, he thought much might be effected in a smaller way to the advantage of the city. For instance, at the head of Bay St., opposite the new city buildings, the corners might be cut away to give an open area, and a fountain or statuary placed in the vacant space. Something of the same kind might be done at the corner of King and Yonge Streets, as it would not cost very much, now while the old buildings remain, to acquire the two north corners and cut them away, leaving a resting spot in the centre.

Mr. Gregg moved in amendment that the Council appoint a committee of members to consider the question of forming a larger committee of citizens.

Mr. Gouinlock thought the matter was one which could be better handled by the "Guild" than by the Association; he was unable to see in what way outsiders were interested in it.

Mi. Paull provoked some laughter by inquiring, "What is the Guild?" or "Who are the Guild?" He had supposed that when the Association was formed the Guild was at an end. He felt assured that action taken by the Association would be more effective than if taken by the Guild.

Mr. Wickson expressed himself in favor of action being taken by the Association rather than by the Guild. He did not think it well for the latter body to bring itself before the public.

Mr. Gouinlock said that leaving the Guild entirely aside, the matter was one of interest only to city architects; it was something referring to the City of Toronto, and not the Province at large.

Mr. Wickson dissented from that view. Other cities in the Province were interested both in the matter of improved fire by-laws and more systematic ornamentation of their open spaces.

The President thought Mr. Gouinlock misapprehended the object of the Guild. That body had no more to do with Toronto than the Young Liberal or Young Conservative Clubs, as it held its meetings merely for social objects. He thought, with the Registrar, that action by the Association as a whole would have more weight. He could see no reason why there should not be a committee having sections in different cities. There was no need of frequent meetings, as action could be had as a result of correspondence.

At the suggestion of the President, after a little further discussion, the following committees were appointed on motion of the Registrar, seconded by Mr. Townsend, to prepare resolutions and report to the Association to-morrow:

On the fire by-law: Messrs. Tully, Gordon and Burke.

On the city ornamentation: Messrs. Billings, Baxter, D. B. Dick, W. R. Gregg, A. A. Post and W. B. Aylsworth.

Mr. A. H. Gregg called attention to the apparently decreasing popularity of the examinations of the Association, there being only 13 students who presented themselves at those held last year. He thought all would admit that the examinations were one of the chief bulwarks of the Association, as they fixed the standard they were attempting to raise. He thought that some tangible recognition in the shape of a diploma given to those who had already passed the examinations, as well as to those who might be successful in passing them in the future, would be an incentive to students to come up to them, and therefore would move, "That diplomas be granted to all students who have passed the final examinations up to the present time, and also to those passing them in the future."

Mr. Baxter seconded the motion.

The Registrar said he had some time ago received a letter in regard to this matter from the mover of the resolution, and it had been spoken of at the Council meeting in the morning, the only question being as to the expense of getting up a diploma of such artistic merit as would be creditable to the Association. He himself thought the idea a good one.

Mr. Billings, referring to the objection of the expense, said that in the civil service men had to pay $7 for their commission, and similarly, a charge might be made for the proposed diploma.

The President asked in the event of non-payment of fees or for other sufficient cause, the diploma, if given, could be withdrawn?

To this there seemed to be a general dissent.

Mr. Wickson thought it a feasible plan to make a charge for the diploma as suggested. He had been surprised to learn that in the medical profession, in certain hospitals at St. Louis, even when medals were earned, they were not given out until a certain amount was paid for them.

Mr. Gordon threw out the idea that one item of the expense be reduced by holding a competition among the members for a suitable design, which would leave only the mechanical part of the work to be paid for.

The motion was then carried.

Mr. Aylsworth said there was a matter rising out of the minutes regarding which he wished to speak. It appeared from the Librarian's report that, while the annual expense of his department continues as usual, the number of books called for had so declined that each loan cost the Association something over a dollar, besides the first cost of books, &c.

Could we afford to be so generous to the few members or students who seemed to appreciate or desire the books?

At a former meeting he had questioned the wisdom of founding a library which must remain so weak and unattractive, and that view had now been confirmed. There is a much more valuable collection of architectural works in the Toronto Public Library, free to all. The library of the Provincial Parliament contains a number also easily accessible, and the School of Practical Science has here a magnificent collection, not only of books, but photographs and plates of everything worthy of study. This collection is growing and is freely offered for our use and benefit. Would it not then be a graceful act to offer the donation of our small library to be added to that of the School?

Mr. Paull depreciated the tendency to despise the day of small things, and could not believe that Mr. Aylsworth was serious in his proposition. Speaking for himself, he would rather give a subscription for the purpose of increasing the efficiency of the library.

Mr. Aylsworth assured the last speaker that he was quite sincere in what he had proposed. It did not seem feasible to maintain a library that would be serviceable to an Association whose members were scattered all over the province. Then again there were so many libraries started in the city that not one of them was what it might be. He would like to see all the books on architecture now scattered in the various libraries brought together where they would be more accessible and consequently more made use of.

Mr. Helliwell seconded Mr. Aylsworth's motion, expressing his concurrence in the views of that gentleman regarding the desirability of concentrating the works on architecture now scattered in different libraries in some one place at which members of the Association might avail themselves of them for reference, and could also have the privilege of taking them out if necessary.

The Registrar reminded the members that as the Association held examinations, it ought to have a library that at least embraced all the text books necessary to the examinations. The lack of these books had been made an excuse for not coming up for the examinations.

Mr. Paull stated that he had learned from the chief librarian that the medical books in the reference department of the public library had been handed over to the medical profession and he thought proper action and representations would result in similar action by the architectural works being handed over to the custody of the librarian of the Association.

Mr. A. H. Gregg thought the committee should consider the desirability of enhancing the utility of the library rather than wiping it out of existence.

The President said he understood Mr. Aylsworth's motion to be that the committee should consider the propriety of doing away with the library.

Mr. Aylsworth said his motion was that the committee should take into consideration the subject of the library, and bring in a resolution to deal with it one way or the other.

The motion was then carried and the President nominated

the following committee to consider and bring in to-morrow a report concerning the future of the library: Messrs. Aylsworth, Wright, Wickson and A. H. Gregg.

Mr. Aylsworth then read a paper entitled "A Chapter from my Note Book—Building Methods in Rome," which will appear in our March issue.

The President asked how the vaults referred to by Mr. Aylsworth were held together.

Mr. Aylsworth presumed they were built a good deal in the same way as bakers' ovens. In the case of a room 15 feet square or thereabouts, a scaffold might be erected and covered with sand and the vault formed over that. In some cases they were of brick work, but not at all carefully done, seeming rather to depend on the strength of the mortar.

The Registrar stated that the Italian vault was something he had had an opportunity of seeing something of, having been shown through a mansion at Florence, owned by an American, who had described to him the way in which it had been built. Every floor was vaulted with an elliptical brick vault. The walls were not very thick, as even the top floor, which was unused, had the benefit of a good deal of vertical wall. It had occurred to him that the process was one which might be adopted in other countries, even our own. The process of vaulting, as described to him, was to outline on each wall with chalk the form the vault was to take; then to mark the courses on these outlines and stretch strings across, laying the courses to the string as in ordinary walling. Every third or fourth brick was propped up by a stick from the platform the bricklayers were working from, until the course was completed and held itself. The bricks were not laid as in an arch, but edge to edge, and as the Italian brick is thin the vault was not more than two inches in thickness—and this over quite a large room. The moment the last brick was in, while the mortar was still new, the workmen got on the back of the vault to continue building. On one occasion a derrick pole had fallen and broken through the crown of each floor, but only made a small hole. If fire-proof building is to be talked about a construction of this kind might well come in for consideration.

Mr. Aylsworth said there was no reason why we should not have fire-proof buildings, using concrete more than we do. He believed in California they used concrete beams in which sufficient iron rods were laid and the concrete floor laid at the same time.

SECOND DAY.

The convention resumed its session at 10 o'clock a. m., when Mr. D. G. Baxter, of Stratford, read a paper on "Points on Acoustics," which will be printed in a later issue.

At the close of Mr. Baxter's reading the President called on the members for any remarks they might have to make on the subject, and the Registrar suggested that the President, having a wide experience in the erection of churches, would be able himself to give the convention some valuable information.

The President said one method he had found very effective was to have a flat wall behind the speaker. He had known instances where by reason of an octagon form behind the speaker, the echo had been such that he could hardly be heard, and this was in a great measure remedied by cutting off the octagon.

Mr. Wickson enquired if there was not some theory about the ellipse being the most perfect form; he had been given to understand that it was, although he had not found any authority for the statement.

Commander Law remarked that the Mormon Temple at Salt Lake City, Utah, was said to be almost perfect in its acoustic properties, and was shaped like half an egg.

Mr. Edwards added that the form of the pavilion at Grimsby Park was suggested by the Mormon Temple referred to by Commander Law, but although, as that gentleman had said, the Salt Lake building was believed to be acoustically the most perfect on the continent, the Grimsby imitation bore the reputation of being the very worst in that respect.

Mr. Wickens said he had heard it remarked by a musician that any building which was good to speak in was poor to sing in. It seemed almost universal that a church or any building which pleased singers was not one that pleased speakers.

The Registrar suggested that if the choir was placed in a recess of resonant wood above the level of the speaker, he would not be effected.

Mr. Baxter said the objection to seating the choir in a groined recess behind and above the speaker was, that it formed a volume of air behind him which he had to maintain in vibration all the time he was speaking and which weakened the sound. The higher the recess could be raised behind the speaker the better. He had noticed one church in which the chior was directly above the speaker, the front of the chior gallery being brought out about four feet, the under side of it forming a cove, which to a great extent kept the sound vibration directed from him out to the audience, and leaving a clear and sympathetic vibration which did not affect the main church at all.

Mr. Edwards agreed with the essayist that it was difficult to formulate any definite laws on the subject of acoustics; it was a case in which "doctors differ." The whole theory of wave sound was doubted by some, who adduced very good reasons in support of their unbelief, contending that it takes so much effort to set in motion the atmosphere which is the means of communication, or which is the matter on which the wave sound has to act. As an illustration of that they contended the distance the sound of a grasshopper is heard would require tons of power to produce the wave sound at such a distance if the wave theory were correct. That being the case, it was necessary to look carefully at the beginnings on this subject, and to avoid building up any superstructure before the foundations were securely laid, and he thought the foundations of the matter required some further negotiation yet.

Mr. Geo. Browne (of Winnipeg) related his experience of a church in Winnipeg which on account of its great height was very defective in acoustic properties, and in which it was almost impossible to speak effectively. It was at last decided to take down the building and re-erect it on the same foundations, but with the height greatly reduced, and after that was done the pastor stated that whereas the old church was one of the very worst he had spoken in, after being so rebuilt it was one of the very best. He thought this demonstrated that not only length and width, but height also, had a very important bearing on the subject of acoustics. He had this summer completed a Presbyterian church, which was built exactly square, about sixty-five feet square, in which he had adopted the American system of placing the preacher in a corner. It had a gallery on two sides and coved plaster ceilings, and the tie beams formed deep panels in the ceiling. The result had been one of the finest buildings for speaking in the city, so much so that whenever religious meetings were held requiring a building with good acoustic properties, the persons interested tried to get this church to hold them in. In the Convocation Hall of Manitoba College they had a hall 65 x 35 feet, and he was told by the principal that he found no difficulty whatever in speaking in it. There was a gallery at one end of the room and a coved ceiling. From his experience he believed that the coved ceiling aided very materially in causing the sound to travel freely throughout the hall.

Mr. Wickson asked if a coved ceiling at the end of an audience room opposite the speaker had the effect of causing an echo.

Mr. Browne said he always continued the cove all around the building; he thought it reflected the sound.

Mr. Baxter said he had observed in nearly all the Chicago buildings that the cove on the rear wall was far deeper than around the sides, in fact they drew the cove line right round so that the entire body of sound was directed right down, and there was no chance for the formation of an echo, whereas, if there were any straight line between the curve and the floor of the gallery, it would not have so good an effect.

Mr. Paull said an important matter was what should be the limit of size in a church in order to secure proper acoustic qualities. He had heard it said that 1200 persons was the greatest number that could be accommodated so that the preacher could command their hearing. The church in Winnipeg spoken of by Mr. Browne as 65 feet square would have about that capacity. He would like to ask Mr. Browne how the extremities of the panels in the ceiling of that church were finished? Were they coved at the ends.

Mr. Browne stated they they were finished simply by running up a false rib. The tie beams came across and then they ran them down on the cove to a small projecting cornice.

The President stated that in regard to the remarks of Mr. Edwards about the grasshopper, he thought it was necessary to take into consideration the number of vibrations in the air; he supposed the more rapid the vibrations of the air the more penetrating the sound would be.

Mr. Edwards said he had not the confidence in coved ceilings that had been expressed by some of the members. He had in his mind a large room or auditorium which was almost as bad acoustically as the Grimsby temple, the ceiling of which was very deeply panelled and with a very extensive cove and all the other features which had just been pronounced of no great advantage. It was really a most miserable place to speak in. At one time the platform was placed on the long side of the building, but the echo was so bad that it had to be changed to the other side, which produced slight improvement, though it was not perfect by a great deal yet. These things did not always work in accordance with one's preconceived ideas. He had happened to have a building somewhat similar to the Winnipeg church rebuilt by Mr. Browne, and he had recommended putting in a gallery, which he hoped would remedy the trouble that existed.

Mr. Browne said he regarded a gallery as necessary to secure good acoustic properties in a church. Another matter he wished to mention was that the windows in Westminster church had circular heads, cutting into the cove, just the same as a vault or groin, and he would not at all wonder but that assisted the sound.

Mr. Edwards said one of the best auditoriums he had ever been in, speaking from the acoustic point of view, was the Casino, of New York, which was built very much after the style of the Massey Hall in Toronto, only the recesses were much deeper all round. This had a very beautiful effect from the artistic standpoint, as well as being very beneficial to its acoustic properties.

The President said that in view of Mr. Browne's opinion that a gallery was necessary to good acoustic properties in a church, it would be interesting if any one could tell what had been the effect in St. James Cathedral in this city, from which the galleries had lately been removed. He thought an instance of the detrimental effect on good acoustics of a high ceiling was to be found in the chamber of the Parliament Buildings in Toronto, which was one of the worst rooms possible for hearing in.

Mr. Wickson facetiously suggested that that might be due to the influence of having been designed by an American architect.

Commander Law asked if the Massey Hall was regarded as a good building acoustically, and what effect the "gingerbread" work had on its acoustic properties.

Mr. Edwards said he had no knowledge of the acoustic properties of the building referred to, and had only spoken of it with reference to its structural resemblance to the New York Casino.

Mr. C. H. C. Wright, Lecturer in Architecture at the School of Practical Science, then read an interesting paper on "Portland Cement," which is printed elsewhere in this issue.

A paper was also read by Mr. McCarthy, which, with the discussion thereupon, will be printed in a future number.

Mr. Townsend, on behalf of the committee appointed to consider the matter of the library, presented the following report:

REPORT OF COMMITTEE APPOINTED TO CONSIDER THE STATE OF THE LIBRARY:

Your committee—while recognizing the absurdity of attempting to furnish the members of the Association with architectural books to read, at a cost to the Association of something over one dollar for each reading, feel that to dispose of the library—constituting as it does one of the strongest bonds of union in the possession of the Association—would be a very serious mistake.

They are of the opinion that, notwithstanding the fact that but few members have availed themselves of the privilege of reference to the books, this privilege is of considerable value to many members of the Association, particularly to those members who are so placed as to be unable to make use of the larger city libraries, and therefore recommend that in place of disposing of the library of transferring it to other institutions, every effort should be made to increase its efficiency, both by purchase of additional books—so far as the funds at the disposal of the Council will admit—and by endeavoring to obtain donations from members and others interested in architectural education.

They believe that books of a strictly technical nature being of comparatively little value to persons outside the profession, a properly circulated appeal might result in considerable increase to the library from bequests and donations from members giving up practice. Such an appeal is meeting with a very hearty response in the society of engineers.

The Architectural Association of the Province is unquestionably a most qualified custodian for architectural works of reference which have become public property, and your committee believes that if the Association library becomes properly established and generally used, it is reasonable to expect that other bodies having control of architectural books will transfer them to the Association, just as the Public Library Board has recently handed the medical books of that institution over to the Medical Association.

They would further recommend that until the finances of the Association are in a better condition, purchases should be confined to books necessary to the students in preparing for their examinations, and those dealing with the most modern methods of constructinn, nature and properties of building materials, and other matters of a practical nature.

In conclusion, they would suggest that the cost of managing the library be reduced to a minimum, and that a circular be sent to all members explaining the conditions upon which the books are loaned.

S. H. TOWNSEND,
M. B. AYLSWORTH,
C. H. C. WRGHT,
A. H. GREGG,
A. FRANK WICKSON.

The President said he had listened to the report just read with more pleasure than to anything else during the present convention.

Mr. Aylsworth moved the adoption of the report, seconded by Mr. Townsend.

The President said he understood it was the intention to send on the report as a recommendation to the Council.

Mr. Townsend replied that was the intention.

The President then asked for discussion on the report of the committee.

Mr. W. R. Gregg suggested that a certain sum of money be each year devoted to the improvement of the library, no matter how small that amount might be.

Mr. Gordon approved of the suggestion, and thought a resolution should be passed to the effect that the yearly revenue over and above the sum necessary for the economical administration of the Association should be applied to increasing the library.

Mr. Townsend thought the recommendation on the subject contained in the report was in better form than that suggested. The Council was certainly in a better position to judge of the financial standing of the Association than the convention could be.

Mr. Gordon thought too many things were being thrust upon the Council, and the members throughout the province consequently felt little responsibility with regard to the work of the Association. He would embody his ideas in a motion that all revenue received by the Association over and above that which is necessary for the efficient administration of the affairs of the Council, should be devoted to improving the library.

Mr. Billings seconded the motion.

The President said the motion could be made after the report had been adopted.

Mr. Power thought Mr. Gordon's remarks pointed in the right direction, and the course he proposed would, as he said, throw the responsibility more on the members, which was desirable in his opinion.

The report of the committee was then adopted.

Mr. Gordon then moved that it be an instruction to the Council that all surplus revenue yearly over and above what is necessary for the efficient and economical administration of the affairs of the Association, be devoted to the increasing of the efficiency of the library.

The President said if there were a surplus of fees over expenses amounting to say $500, it would be rather a questionable proceeding to spend it all on the library.

Mr. Aylsworth said he understood the resolution only contemplated dealing with the revenue of each year. Last year there had been no surplus, but during the coming year it is hoped there would be a small amount.

The motion was then carried.

The members partook of luncheon served in an ante-room of the School of Practical Science at 1 p. m.

AFTERNOON SESSION.

On resuming proceedings at 2.30 p. m., Professor Coleman, of the School of Practical Science, read a paper on "The Weathering of Building Stones," which appears on another page.

Mr. Darling spoke of the peculiar way in which some of the projecting stones in a building erected by him, and in which great care was exercised in selecting the stone, had become damaged, apparently by water soaking through; the exposed surface being perfectly sound and good and the damage occurring where it was perfectly dry. He was unable to understand how the water could soak through.

Professor Coleman inquired if it was a white efflorescence?

Mr. Darling said it was.

Professor Coleman suggested the presence of iron pyrites in the stone.

Mr. Darling stated that it was chosen because of its supposed freedom from iron.

Prof. Coleman expressed his willingness, if furnished with specimens, to endeavor to ascertain the cause of the action.

The President enquired if there was any likelihood of the water soaking through vertically.

Mr. Darling said that was exactly what seemed to have taken place.

Professor Coleman said there must be some soluble salt in it—perhaps a sulphide.

The President had noticed in the Bank of Commerce, that the underside of the Connecticut brown stone of which it is constructed was becoming friable.

Mr. Townsend said there were indications of the same kind in a great many stones in Paris, and the explanation was offered that the water gets into the stone and gets down a certain distance, and not being able to dry out, forms certain salts.

Professor Coleman said unless there was something in the stone that would dissolve that could not happen; there must be some sulphide or something of that kind.

Mr. Power said there was a limestone in Kingston which was affected in the same way, in St. George's Cathedral in that city.

Mr. Billings referred to a similar effect at Ottawa in certain balustrades of Ohio sandstone in the Parliament buildings which had crumbled away.

Mr. Tully said that some years ago his attention was drawn to the yellow sandstone at Osgoode Hall, the balusters at the centre entrance being all decayed away—the surface completely gone. As architect for the Government, it gave him some concern, and he spoke to a painter about it, who invented a paint which was effective in arresting the decay. On finding the paint efficacious he induced the Commissioner to have all the stone work of the building painted with it, because the surface of all the stone was becoming affected in the same way. Some critic in the newspaper had referred to the bad taste displayed in painting the stone work of a beautiful building like Osgoode Hall, but it was a necessity in order to preserve it. He would not advise architects to permit the use of that yellow stone.

Mr. Darling pointed out that in the Molsons Bank and the old Board of Trade building, constructed of Ohio stone, the surface was in almost perfect condition.

The committee appointed to bring in a report in regard to a revision of fire by-laws, then presented a report dealing in detail with several points in which buildings could be better protected from damage by fire.

Mr. Aylsworth was of opinion that some provision should be made that elevators and stairs should be separated as far as possible.

The President suggested as changes desirable in the report the addition of fire proof shutters on all windows above ground floor, on main areas or narrow thoroughfares, and a reduction of

the weight to at least 100 pounds for offices, increasing in buildings devoted to mercantile purposes.

Mr. Aylsworth was opposed to the report in its present form being adopted. It might serve as a recommendation or suggestion to a committee who should give it more time than could be spared now in convention.

Mr. Power was in favor of taking more time to consider the matter, so as to prepare a by-law carefully that could not be picked to pieces. He thought the committee in the time at its disposal had done well, but he would like to see a little more time allowed for consideration.

Mr. Symons thought the report could only be regarded as a partial report, and advocated giving the matter further consideration. He moved that the whole matter be referred to a committee of city architects to be named by the President for further consideration.

Mr. Gouinlock seconded the motion.

Mr. Darling thought it advisable to have as wide a discussion as possible regarding so important a matter; he thought too much time could not be expended on it. He felt that in the short time that could be devoted to it now a satisfactory conclusion could not be reached, and he did not deem it wise to adopt the report in its present shape as an expression coming from the whole Association.

Mr. Gregg thought the discussion so far had shown that there were many additional points to be considered, and he supported the motion of Mr. Symons, that it be left to a local committee to consider it in all its respects, including the state of the present city by-law.

Mr. Symons' amendment was then carried.

The President requested the former committee to retain the matter in their hands and to place it in as good shape as possible, and then to call a meeting of the city members to further discuss it.

A paper entitled "Electricity for Architects," was then read by Mr. John Langton, which is published elsewhere.

Mr. Aylsworth then presented the report of the temporary committee on the improvement of cities, approving of the idea and suggesting the appointment of a permanent committee for carrying it out.

On motion of Mr. Aylsworth seconded by Mr. Baxter, the report of the committee was adopted.

The Civic Adornment Committee was then appointed by the President, as follows:

For Toronto, Mr. Aylsworth and Mr. D. B. Dick; for Kingston, Mr. Power; for Hamilton, Mr. Edwards; for Stratford, Mr. Baxter; for Ottawa, Mr. Billings, with power to add to their number.

EXHIBITION OF WORK BY MEMBERS.

A number of slides prepared from drawings and photographs of designs by members were then exhibited by means of the stereopticon, and as the views were thrown on the wall comments were made by the meeting upon points in the design of the buildings. There were about eighty slides exhibited and much interest was shown.

On motion of Mr. Gouinlock, seconded by Mr. Belcher, the thanks of the Association were tendered to Mr. C. H. C. Wright for preparing the slides for the views shown.

ELECTION OF OFFICERS.

Messrs. Post and Helliwell having been appointed scrutineers, the President suggested that it be a recommendation that retiring members of the Council shall not be eligible for one year after their period of service.

Mr. Edwards moved that the Association adopt the suggestion made by the President.

Mr. Gordon seconded the motion, which was carried unanimously.

The election was then proceeded with, and the following gentlemen declared elected as members of the Council: Messrs. F. J. Alexander, of Ottawa, G. M. Moore, of London, and W. R. Strickland, of Toronto.

Votes of thanks were passed to the Minister of Education for the use of the building; to Messrs. Galbraith and Wright and the members of the School of Practical Science for assistance on this and other occasions; to Professor Coleman, Mr. John Langton and Mr. Hamilton McCarthy for their valuable papers.

The convention then closed.

THE DINNER.

Following their usual custom, the Toronto members of the Association gave a dinner in honor of the non-resident members. The event took place this year at McConkey's restaurant, at the close of the Convention. About fifty members and guests participated in the enjoyment of the many good things, of a physical and intellectual character, which the occasion afforded.

THE ARCHITECTURAL GUILD OF TORONTO.

At the annual meeting of the Architectural Guild of Toronto, the following officers were elected: Sec.-Treasurer, Geo. W. Gouinlock; Trustees, D. B. Dick, Henry Langley; Executive Committee, W. R. Strickland, Com. F. C. Law; Auditors, S. H. Townsend, C. H. C. Wright; Representatives on Technical School Board, Edmund Burke, A. F. Wickson.

PORTLAND CEMENT—A PLEA FOR A GREATER UNIFORMITY IN THE TESTS AND SPECIFICATIONS.*

By C. H. C. Wright, B. A. Sc.

At the present time when the American Society of Civil Engineers are using a uniform system of testing and the Canadian Society of Civil Engineers is endeavoring to get its members to work along more uniform lines, it may not be out of place for me to draw your attention to this question.

In a publication of last year (1893) by Geo. L. Sutcliffe, Associate R.I.B.A., on "Concrete," we find the following:—"The variety of specifications for Portland cement is somewhat bewildering." He is speaking of English specifications. This is not so in Germany, for there they have standard regulations. In England they are taking steps to remedy this evil, and there is no reason why we in Ontario should not do likewise.

The object in testing Portland cement is not that pursued in testing other materials of construction, viz: to determine their absolute strength, except in a few special circumstances—the reason being that the cement is seldom employed where it is subjected to stresses in the vicinity of its safe load. What we do wish to know, however, is that the cement will set, harden and continue to increase in strength, and not subsequently disintegrate or blow. Many of you have heard the statement that there is no use in testing cement, as the proper test is experience. There is no doubt but that the test of time in any actual construction is the very best, but how expensive when the material proves a failure. Or again, having proved that a particular brand is good, we are uncertain but that the very next shipment may prove to be utterly worthless, as illustrated by the following cases in the laboratory of the School of Practical Science: In August, 1894, there were two samples of the same brand of German Portland cement. The first was unfit for use, while the second was an excellent cement. In June and July, 1893, there were two samples of the same brand of English Portland cement—the first being unfit for use, while the second was a good cement. In February, 1892, there were two samples of Canadian Portland cement—the first being unfit for use while the second was a cement of excellent qualities.

I have made the above classification because it is very common in Ontario at the present time. We are then expected in the laboratory to make certain observations and from these predict the most probable behavior of the Portland cement in the work under construction. In order to determine with any degree of certainty the properties of a Portland cement, the observer requires from 1 to 3 months, as will be shown later, but unfortunately in practice in Ontario he has but a week or two at his disposal. The observations usually made are: 1. Fineness of grinding; 2. Tensile strength; 3. Soundness; 4. Specific gravity or weight, the latter being omitted quite frequently, while we have occasionally added chemical analysis, compression and transverse tests.

With a complete knowledge of the above we are able to say what may be expected of the samples of Portland cement under consideration.

Fineness of Grinding.—It has been demonstrated and admitted for some considerable time by all who use Portland cement, that any particles which will not pass a No. 50 sieve, i.e., 2500 meshes per sq. inch, are inert and act as sand. It is now, however, generally held that particles not passing a 100 sieve are inert. From this point alone it will be seen that the question of fineness is a very serious one. The cement in practice is mixed with definite proportions of sand; is it not therefore of first importance to know how much sand is already in the barrel labelled "Portland Cement?" Further, as the duty of the resulting fine cement is to form an envelope around the particles of sand and unite them together, it follows that the finer the grinding the less the amount of cement required, or the greater the amount of sand which may be mixed with it. One of our English authorities, Mr. H. K. Bamber, in discussing this point says, that these large particles (retained in a No. 50 sieve) not only remain inert while the cement around them is setting, but after the process of hardening is well under way, they absorb water, causing internal expansion and the disruption of the cement in the same manner as small lumps of lime disintegrate.

Mr. W. F. Reid says he had not been able to produce such expansion experimentally, and did not think it took place in good cement. Whether it is true or not that these particles do afterwards absorb moisture to the detriment of the cement, it is still desirable to have the cement properly ground, and the German and Canadian manufacturers are paying special attention to this question.

The majority of English cements that we receive in Ontario are not properly ground. While on this point I would like to say that the spirit of our Canadian manufacturers as evinced in this matter of grinding is deserving of commendation—for they have done this in the face of the following facts: (1) the consumer—our architects and engineers—are willing to accept a much more coarsely ground cement than they are producing; (2) that the more coarsely ground cements stand a higher tensile stress than the finer ones when tested neat; (3) that the coarser a cement the higher its weight per striked bushel; and (4) that

*Paper by Mr. C. H. C. Wright, B. A., Sc., School of Practical Science, Toronto, read at the fifth annual convention of the Ontario Association of Architects.

the expense of grinding is very considerable. I would like to urge upon you the propriety of so writing your specifications as to induce the manufacturer to produce a better article instead of tempting him to do otherwise.

It is apparent then, that while they have been under a much greater expense in producing an article which they think a better one, and is as a matter of fact better, they have produced a cement which, when tested by you, has appeared worse than if they had not so improved it.

FINENESS OF GRINDING.

	Residue in percentage on sieve No. 100.	Residue in percentage on sieve No. 80.	Residue in percentage on sieve No. 50.
Averages of 180 determinations of German Cements of various brands	8.9	3.9	0.9
Averages of 210 determinations of Canadian Cements of various brands	10.5	3.9	1.7
Averages of 450 determinations of English Cements of various brands	23.7	16.3	9.56

The following might be quoted as instances of the grinding of Canadian Portlands:—

	Residue No. 100 sieve.	Residue No. 80 sieve.	Residue No. 50 sieve.
Star (Deseronto)	5.4	1.8	0.6
Sampson (Owen Sound)	13.9	7.4	3.7
E.P.C (Marlbank)	9.8	4.0	1.0
R.W. (Hull)	11.3	3.3	1.2

In the writer's opinion, the cement should completely pass the No. 50 sieve and leave a small residue on the No. 100 sieve. This, however, is out of the question, considering the present market, but we ought to refuse a cement if the residue on No. 50 is greater than 5%, and after every year or so it might be reduced until the desired end is reached.

I might say that the average requirements of the architect and engineer of Ontario is that the residue on a No. 50 sieve shall not exceed 10%, but I am equally certain that the cement would not be refused if it left a residue of 12 or 13%. There are specifications in this province calling for a cement with a less residue than 20%—in fact the text-book as set by this Association mentions 20%. It is time we were following the example set by our manufacturers, and encourage them to grind as we like and not as they please.

TENSILE STRENGTH.

The method of determining the tensile strength most commonly followed in Ontario is to mix a little water with the cement, then place it in a mould and leave it in the air for 24 hours, after which the briquette is placed in water and kept for six days; it is then broken and the strength determined. In a few cases (in Ontario), in addition to the above neat test, a sand test is made. Simple as the above seems, there are many conditions which affect the strength very materially. Among these may be mentioned:

1. The fineness of grinding.
2. The percentage of water used in gauging.
3. The thoroughness of the gauging.
4. The style of grip used in breaking the briquette.

In support of the fact that the fineness has a material effect upon the resulting tensile strength, I would quote the following results from a paper read before the British Institute of C. E., by Mr. Grant.

Quality of Cement.		Ult. ten. strength at 3 mo.				Ult. ten. strength at 6 mo.			
		Neat.	1 sand 1 cem.	2 sand 1 cem.	3 sand 1 cem.	Neat.	1 sand 1 cem.	2 sand 1 cem.	3 sand 1 cem.
Fineness, &c.	w't per bus.	Pds. sq. in.	Pds. sq. in.	Pds. sq. in.	Pds. sq. in.	Pds. sq. in.	Pds. sq. in.	Pds. sq. in.	Pds. sq. in.
Cement as received from manufacturer.	116	504	286	117	103	527	350	229	151
The same passed thro' a sieve of 1296 meshes per sq. in., which rejected 20 per cent.	102	457	324	212	143	492	424	281	173
The same passed thro' a sieve of 2500 meshes per sq. in., which rejected 30 per cent.	99	449	377	256	173	486	439	323	228

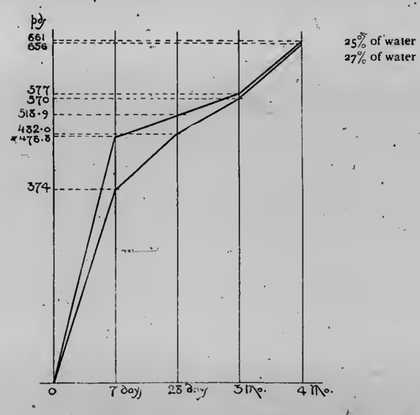
By referring to this table it will be seen that if gauged neat, coarse grinding increases the tensile strength, while if gauged with sand, coarse grinding decreases the ultimate tensile strength.

A. E. Carey, M. Inst. C. E., gives the following results gauged 3 sand to 1 of cement:

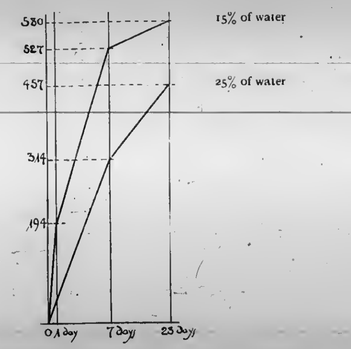
As ground with 9% residue.	Pds. per sq. in.
On a No. 50 sieve (2500 meshes per sq. inch)	220
With residue on 2500 sieve removed	304
" " 5625 " "	311
" " 32,257 " "	360

While in the longer tests the percentage of water used in gauging may have very little effect upon the tensile strength, yet for the ordinary 7 day or 28 day tests of neat cement, the amount of water used will alter the strength between wide limits. The less the amount of the water used and the firmer the cement is pressed into the moulds, the stronger the resulting briquettes, as the following tests made in the laboratory of the School of Practical Science will show.

The following diagram gives the record of the averages of 200 briquettes of Owen Sound Portland, gauged neat, one half being gauged with 22 per cent. (by weight) of water, and the other with 27. As will be noticed the difference between the two gaugings is very marked at 7 days, gradually growing less as far as the experiment lasted.



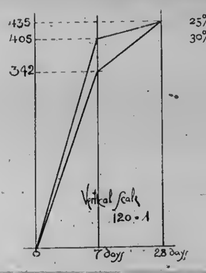
Sieve.	Residue in percentage by weight.
No. 100 (10,000 meshes to the sq. in.)	13.9
No. 80 (6400 " " ")	7.4
No. 50 (25,000 " " ")	3.7



The above diagram gives the averages of 50 briquettes of Hull Portland gauged with 15 and 25, 6 per cent. of water.

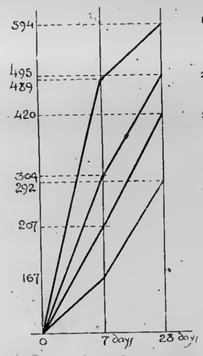
Sieve.	Residue in percentage by weight.
No. 100	41.3
No. 80	32.8
No. 50	22

It should be mentioned here that this series of tests was made some time ago, and that the grinding of this brand is much improved.



The above diagram gives the averages of 40 briquettes of Star (Deseronto) Portland, gauged with 25 and 30 per cent. of water. This sample was very fast setting so that the amount of water used is larger than in the two preceding cases.

Sieve.	Residue.
No. 100	6.1
No. 80	2.55
No. 50	1.225



The above diagram gives the averages of 80 briquettes of White's Portland gauged with 15.3 – 23.7 – 27.8 and 33.3 per cent. of water.

From all of these diagrams it is readily seen that the amount of water used has a very marked effect upon the tensile strength at the end of seven days, and that this difference gradually becomes less in time as far as the experiments are carried.

In making briquettes of neat cement not more than 1 or 2 should be attempted at once, for the water and cement must be thoroughly incorporated, and yet placed in the mould before any initial setting takes place.

From a paper prepared by G. F. Deacon for the British Inst. C. E., we get the following:

In discussing the personal errors in cement testing, Clifford Richardson, Ass. Am. Soc. C. E., gives the results of the following tests made under his supervision. A batch of cement mortar (2 to 1) sufficient to make 45 briquettes was mixed by one individual and divided into three equal portions. The mortar was then handed over to three persons (⅓ to each) to be placed into the moulds. Observer A was unskilled in making briquettes; observer B had considerable experience, but no extended practice but endeavored to follow C, who has been engaged for years in making briquettes. A filled his 15 moulds and had mortar left, B crowded his into 14 moulds, while C just filled 15. The briquettes were treated exactly alike by the same dividual after the gauging, with the following results:

AGE OF BRIQUETTES.	Round Top Cement.			Antietam Cement.		
	A	B	C	A	B	C
7 dy.	64	127	138	47	91	58
28 dy.	122	196	255	139	189	171
3 mo.	175	315	399	147	201	204
6 mo.	258	345	363	150	214	221
12 mo.	340	365	411	146	219	230

That the style of the grip used in breaking the briquettes has a very decided effect is well established by the following table, taken from the report of a sub-committee of the commission of French government engineers. The increase in tensile strength due to the rubber cushioning will also be noted:

TABLE SHOWING COMPARATIVE REGULARITY AND STRENGTH OF FRACTURE OF NEAT CEMENT BRIQUETTES BROKEN WITH JAWS OF GRIPS UNPROTECTED AND CUSHIONED WITH RUBBER.

UNPROTECTED.				CUSHIONED WITH RUBBER.			
Eccentricity of Fracture.	Sectional Area* of Fracture in sq. inches.	Resistance per** sq. inch of Minimum Section in pounds.	Resistance per sq. inch of Fracture in pounds.	Eccentricity of Fracture.	Sectional Area of Fracture in sq. inches.	Resistance per sq. in. of Minimum Section, in pounds.	Resistance of sq. inch of Fracture in pounds.
+7.5	.937	426	352	−6.0	.850	496	455
+0.5	.796	398	386	+1.5	.791	461	448

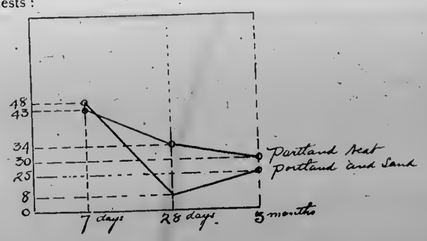
+8.0	.892	489	426	−2.0	.797	447	432
+1.5	.795	454	441	−4.5	.823	483	452
+2.5	.813	418	447	−1.5	.797	475	461
−6.0	.824	496	467	+3.5	.831	475	441
+2.5	.813	432	414	−1.5	.761	390	398

*In computing this area the air bubbles have been taken into account.
**The Minimum Section is exactly .775 sq. inch.

AVERAGES OF 384 TESTS OF PORTLAND CEMENT AND PORTLAND CEMENT CONCRETE, PLACED IN SITU AT VARIOUS INTERVALS OF TIME.

Number of minutes between mixing and moulding.	0	5	10	15	20	25	30	35	40	45	50	55	60	70	80	90	100	110	120
144 briquettes of neat cement and cement and Oporto gravel tested. Neat at—7 days.			263		262		258		257		258		261	258	253	242	251	249	23
Concrete—14 days.																			

The following table gives the losses in per cent. due to the retempering of cement and is the average of a large number of tests:



The conclusion of the committee was that they consider the use of rubber cushioning tends to regulate the position of the fracture and the ultimate strength.

Similar tests by American engineers might be quoted, but this is not necessary. Mr. Jno. Gartland found from a large range of tests that where only 50 per cent. of the briquettes broke across the least cross section with the unprotected grip, 90% broke across the least section while using rubber cushioning with the grip designed by Mr. W. R. Cook, representative of Messrs. Riehle Bros. This is the form of grip used in the School of Science.

In this connection might be mentioned a series of tests in the school laboratory on the effect of cushioning. 50 briquettes were broken in sets of five, and in each case the cushioning was increased, with the result that the tensile strength increased, as given below:

	Pds. per sq. inch
1 set, average	328.8
2 " "	344.3
3 " "	344.3
4 " "	355.6
5 " "	363.
6 " "	369.5
7 " "	395.2
8 " "	393.3
9 " "	396.2
10 " "	405.7

It is apparent, then, that the resulting tensile strength will depend very materially upon the apparatus used, the method adopted and the person employed to perform the experiment. There cannot, therefore, be the same uniformity in specifications on this point as on that of sifting, but much might be done with this end in view. We have already seen in the results quoted variations in the tensile strength at the end of seven days (tested neat) of from 500 pds. per sq. in. to 200, and that these differences may be due entirely to the method of handling. Hence the mere statement that the tensile strength was found to be 345 pds. is meaningless unless we know the method of handling.

In the annual report of the City Engineer, Toronto, for 1893, there is a table giving the tensile strength (tested neat) on seven days of 23 different brands of Portland cement. The average strength of these brands is about 236 pds. per sq. in., the maximum being 350 and the minimum 140. The report for 1890 explains the method adopted. On the other hand, the specification for the drill hall at Toronto calls for a cement to stand a tensile strain of 450 pds. per sq. inch.

Of these two methods the second will, perhaps, give more uniform results, while the former requires less time, and where a large amount of testing is necessary, time forms an important factor. It would, however, be better for all to adopt some intermediate method.

3. SOUNDNESS.—Mr. Faija advocates the use of an apparatus called a "steamer," and which, he claims, will reveal any "blowey" tendency in cement. The test consists in keeping pats of cement in water at a temperature of from 110 degs. to 120 degs. Fahr. for two days.

In a paper prepared for the Engineers' Congress at Chicago, two years ago, Mr. Gary gave in detail the standard methods of testing cements in Germany. All hot tests are discarded there, for the reason, he says, that they are misleading. The American Society of Civil Engineers do not recommend an accelerated test, while the Canadian Society of Civil Engineers recommend Faija's hot test. The fact that many cases of unsoundness in cement are not discoverable by the ordinary short time tests, is well known, and as the hot tests are on the safe side, it might be well for the O. A. A. to follow the suggestions of the Can. Soc. C. E.

SPECIFIC GRAVITY OR WEIGHT.—In the process of manufacture, it is very important that the cement be properly burnt (semi-vitrified). Now, as an underburnt cement is light, it follows that the relative weight forms a ready means of determining whether the burning has been properly done. It has therefore been customary in specifications to state that the cement shall have a definite weight per striked bushel, 112 to 115 pds. However, it would be better to specify that the specific gravity shall be above a certain standard, as the determination of the specific gravity is by no means as uncertain as that of weight. The weight per bushel is unsatisfactory, as it is affected by the following:—1. The size of the measure adopted; 2. The distance the cement falls into the measure; 3. The freedom with which it falls; 4. The looseness or amount of separation between the grains; 5. Any disturbance in the way of a jar while the measure is being filled.

In proof of the above, we may give the following quotation from "Notes on Building Construction," prepared by the Council on Education, South Kensington:—"Method of Weighing"—"In order that the cement may be accurately weighed, great care must be taken in filling the measure. This may be done by allowing the dry cement to run down into the measure by a board or shoot, inclined at an angle of 45 degs., any superfluity being carefully struck off by a light straight-edge. A vessel with holes in it is sometimes used for filling instead of the inclined shoot. An accurate method is to fill the measure through a sieve of about 1-16th inch mesh, held a short distance above it, or the cement may be poured through a hopper placed about two feet above the measure. A drawing of the hopper is sometimes given in connection with the specifications." It is thus apparent that the weight per striked bushel is liable to vary and must differ considerably with different persons and even with different determinations of the same person. The specific gravity, on the other hand, is a definite quantity not effected by voids and its determination liable to but a slight personal error of the observer.

It will be seen, then, how desirable it is that this property of cement, namely, its relative weight, should be determined from its specific gravity rather than from its weight per striked bushel.

The following is the result of a series of tests of Beams 4" × 6" made of Portland cement and kept under water for one year. The first set were gauged neat, while the second consisted of two parts of crushed granite, such as used in the manufacture of granolithic sidewalks, to one of Portland cement:

I.

Span in inches.	Section b h	Modulus of Rupture in pds. per sq. in.
36	4" × 5.9"	526
18	4 × 5.9	426
18	4 × 5.9	594
9	4 × 5.9	542
9	4 × 5.9	361
9	4 × 5.9	518

II.

36	4 × 6	1088
18	4 × 6	1107
18	4 × 6	1007
9	4 × 6	1125
9	4 × 6	1130
9	4 × 6	1111

Compressive strength of two cubes of neat cement one year old:

Height.	Area exposed to crushing.	Crushing strength in pds. per square in.
5"	5 × 4.9	3878
5"	5 × 4.8	3877

THE ACCIDENT AT THE MONTREAL STREET RAILWAY BUILDING.

MONTREAL, Jan. 23rd, 1895.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—In the January number of the CANADIAN ARCHITECT AND BUILDER, there appears a letter signed by E. C. Hopkins, relative to Mr. Lacroix's signature being attached to a report on the collapse of the Montreal Street Railway building, which was prepared by me for the Provincial Government, as follows:—

"It may perhaps be somewhat of a surprise to you, as it certainly has been to Mr. Lacroix and myself, to find his name attached to a report which, as he states in his letter to me, given below, he did not sign, and was no party to; and further, which arrives at conclusions he has not yet gone into or expressed any opinion upon.

What object was to be gained by tacking the 'City Building Inspector's name to the report, without his knowledge, is left for those doing so to explain, if possible."

In explanation of the same I beg to draw your attention to the fact that the report in question was prepared solely by myself, that Mr. Lacroix never was asked to sign the report—in fact, never saw it. We visited the building together, took the bricks and mortar from the wall, and were present at the test at the McGill University Laboratory. After that I was specially requested to prepare a report giving the weights concentrated on the wall where it was supposed to have failed, which I did. Neither the report nor the copy bears Mr. Lacroix's signature, so it was as much a surprise to me as to any one else to find the Building Inspector's name added to my report. As Mr. Hopkins wishes to know "what object was to be gained by attaching the City Building Inspector's name to the report without his knowledge is left for those doing so to explain if possible," perhaps the CANADIAN ARCHITECT AND BUILDER will give the explanation, and by so doing will prove that I at least had nothing whatever to do with it.

Yours truly,

W. McLEA WALBANK.

[It lies with the correspondent of the ARCHITECT AND BUILDER to explain the addition of Mr. P. Lacroix's signature to a report published in the December issue of the CANADIAN ARCHITECT AND BUILDER, and submitted by Mr. W. McLea Walbank, architect, of this city, on behalf of the Provincial Government in the coroner's enquete, of the accident which happened to the Montreal Street Railway Co.'s building. The correspondent of the ARCHITECT AND BUILDER having applied to Mr. Walbank for a copy of his report for publication, the last named referred him to his clerk, who gave him a rough draft of the report and which they together corrected to agree with the original. Mr. Lacroix having examined the collapsed building jointly with Mr. Walbank and the fact of him having also signed a letter sent to the Queen's Attorney and prepared by Mr. Walbank suggesting the proceedings that should be adopted for conducting the tests of the building material employed in that building, led the clerk to confuse the two documents, the letter of suggestions and the final report of Mr. Walbank, and so one was taken for the other, and the name of Mr. P. Lacroix, Building Inspector, added to the report without Mr. Walbank's knowledge, or without any bad faith or intention whatever on the part of either Mr. Walbank's clerk or the ARCHITECT AND BUILDER's correspondent.]

ELECTRICITY FOR ARCHITECTS.*

By John Langton, Toronto.

THE engineer or architect will find that, though the quantities dealt with in electrical work may be new to him, the ideas involved are largely the same as he is already familiar with in other branches of physical science. There is a common impression to the contrary, and this no doubt is partly due to the peculiar names of the practical electrical units: volt, ampere, &c.

These are merely arbritary names, agreed upon by international convention, to shortly express compound units, and so avoid the repetition of cumbersome phrases. It is, for instance, as if it were agreed to call the ordinary British unit of fluid pressure a Newton, so that we might say shortly, but with perfect definiteness, 75 Newtons, instead of 75 pounds pressure per square inch above the atmosphere. Electrical units are in this manner named after eminent men of science. The Volt, after Volta, the discoverer of the galvanic battery; the Ohm, after Ohm, the discoverer of Ohm's law; the Ampere and Culomb, after the French physicists of the same names; the Farad, after Faraday, the Henry after Joseph Henry, and the Watt, the unit of power, appropriately named after James Watt.

In the common commercial uses for electricity for light and power, which the architect has ordinarily dealt with, the main ideas and phenomena present close analogies to the familiar facts of the pressure and the flow of water—so much so that the readiest way of getting a very fair general idea of commercial electricity is to consider the facts concerning it as being illustrated by the similar facts of hydraulics.

I will endeavor briefly to present this analogy, but I must ask you to remember that it is of course nothing but an analogy. I do not mean to imply that an electric current is in any sense a flow of a material fluid, merely that the results are very much as if it were a kind of fluid.

Referring to Table 1:—The 1st column gives the names of the electrical units which measure the four electrical quantities involved in ordinary light and power work. The 2nd column shows the letters by which they are symbolized in formulae. The 3rd column gives the electrical quantities which the units designate. The 4th column states the general ideas involved; and the last column the hydraulic quantities which are analogous to the electrical quantities in the 3rd column.

TABLE 1.

NAME OF ELECTRICAL UNIT.	SYMBOL.	ELECTRICAL QUANTITY.	IDEA.	ANALOGOUS HYDRAULIC QUANTITY.
Volt.	E	Dif. of Potential. Electromotive force (E. M. F.)	Pressure.	Head or pressure of water.
Ohm.	R	Resistance.	Wasteful Resistance.	Friction of pipes and channels.
Ampere.	C	Current.	Rate of Flow.	Flow per second.
Watt.	W	Power.	Rate of doing work.	Power.
			746 Watts = 1 Horse Power.	

OHM'S LAW.

Current = Pressure ÷ Resistance.

$$\text{or Amperes} = \frac{\text{Volts}}{\text{Ohms}}$$

$$\text{In Symbols, } C = \frac{E}{R}$$

$$\text{or, } R = \frac{E}{C}$$

$$\text{or, } E = CR$$

ELECTRICAL POWER.—(Kilowatt = 1000 Watts)

Watts = Volts × Amperes.

In Symbols, $W = EC$

$$\text{or, } W = C^2R$$

$$\text{or, } W = \frac{E^2}{R}$$

As the flow of water is due to difference of level or head, so is a current of electricity due to a difference of electric potential. And in both cases the amount of the flow through some path provided for it, is dependent—1st, on the head or pressure which causes it; and 2nd, on the frictional resistance which the provided path opposes to that flow, and in both cases the work expended in overcoming this resistance appears as heat. With the same resistance, the greater the pressure the greater the flow. With the same pressure, the greater the resistance the less the flow.

In electrical work, the relation between the pressure, the resistance and the current is a very simple one, and is expressed by Ohm's Law, which is that "The current is equal to the pressure divided by the resistance," or that the current is equal to the ratio of the pressure to the resistance. This is a definite numerical statement that the number of the amperes is equal to the number of the volts divided by the number of the ohms. For instance, 100 volts applied to the ends of a wire whose resistance is 50 ohms, will produce in the wire a current of 2 amperes. With 1000 volts and 500 ohms, the current would still be 2 amperes. And the same current of 2 amperes would be produced with 10 volts and 5 ohms.

Now as to the unit of power. In a fall of water, the weight of the water in pounds multiplied by the number of feet fall or head, is its energy—that is, its capacity for doing work—in foot pounds. And consequently, the rate at which this energy is developed, the rate of doing work, that is to say the *power* of the fall, is measured by the rate of flow multiplied by the head. In mechanical units 33,000 foot-pounds per minute is 1 horse power. Whether the flow is 33 pounds per minute under 1000 ft. head, or 1,000lbs. per minute under 33 ft. head, or 33,000 lbs. per minute under 1 foot head, the power in each case is the same, namely: 33,000 foot pounds per minute, or 1 horse power.

Similarly in electrical units, power is measured by the current multiplied by the E. M. F. The watts equal the volts multiplied by the amperes. 1000 volts and 10 amperes, 100 volts and 100 amperes, 10 volts and 1000 amperes, all give the same power, namely: 10,000 watts or 10 kilowatts.

Since it is the same thing that is measured in both cases,—power—there must be a definite numerical relation between the electrical and mechanical units, which is that 746 watts equals 1 horse power.

In buying electric power at a rate of, say, 4 cents per horse power hour, it is a very simple matter to calculate the cost of the current consumed.

* Paper read at the fifth annual convention of the Ontario Association of Architects.

Power circuits supply current at a constant pressure. 250 volts is one usual pressure. If the current used is 3 amperes, the watts are $3 \times 250 = 750$ watts; practically 1 horse power, and costing 4 cents per hour. On a 125 volt circuit, a 6 ampere current would mean 1 horse power. So that for a general rule, multiply together the average amperes, the volts and the hours. Divide the product by 746 and the quotient will be the horse power hours consumed.

The resistance of an electrical conductor is analogous to the hydraulic friction in pipes; but whilst the mechanical friction in pipes varies according to the most complicated rules, the resistance of conductors is fortunately governed by very simple laws. It depends only on the material, the area of cross section and the length of the conductor. And fortunately again a cheap metal, copper, is one of the best conductors. It is second only to silver, which is better still, but only by a small percentage. The resistance of iron is between 6 and 7 times that of copper. Copper is therefore universally used for wiring, and we need only consider the effects of area and length, which are that the resistance of a wire varies directly as the length and inversely as the area.

Suppose the resistance of a wire 1 foot long and of a certain cross-sectional area is 1 ohm; if 2 feet long it would be 2 ohms; if 10 feet, 10 ohms. Another wire of 10 times the sectional area and 1 foot long would be 1-10 of an ohm, or if 10 feet long, 1 ohm. There are plenty of published tables of the resistance per foot of copper wires, and by the aid of this simple relation between resistance, area and length, they may be extended to any actual case. The question of resistance is of direct concern to architects in the wiring of buildings, but its bearing will perhaps be plainer after considering as briefly as possible the three systems of lighting in general use:

I. The constant current system, which is generally used for lighting by arc lamps.

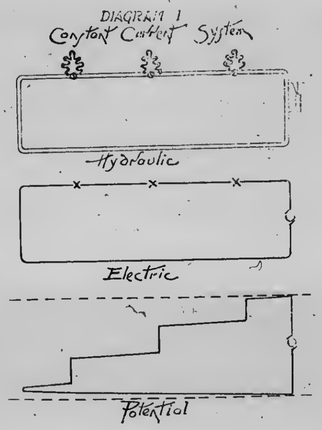
II. The constant potential direct current system, used for incandescent lamps and for motors.

III. The alternating current system, used for incandescent lamps.

These can all be very well illustrated by analogous hydraulic systems, and for this purpose I have prepared diagrams 1, 2 and 3.

Take first diagram 1—the constant current system. Here the pump represents the dynamo, which maintains a steady flow circulating round the

DIAGRAM 1
Constant Current System



main pipe. At intervals in the main pipe are stop cocks, and round each of them a by-pass consisting of a long pipe, which opposes a high frictional resistance to the flow, so that the pump must exert greater pressure to maintain the same steady flow. These by passes represent the lamps, in which the whole work done in forcing the current through them against their resistance, appears as heat, raising the temperature of the carbons to such a degree that they give out light. It is obvious that except for the constant resistance of the main pipe, a resistance which is made small, the work the pump must do increases directly with the number of the by-passes the flow must traverse; and, since the flow is constant, it follows that this increased work is due entirely to increased pressure.

Underneath the hydraulic diagram is that of the corresponding electric system, representing a dynamo and arc lamps. The amperes are the same no matter how many lamps are burning, but the dynamos must generate about 45 volts for each lamp burning.

Underneath this again, I have drawn a diagram of potentials, which shows graphically how the difference of potentials established by the action of the dynamo is consumed in different parts of the circuit. It is as if the dynamo were a pump raising water to a height, from which it flows down through the channels offered by the different parts of the circuit back to the pump, which again raises it to retrace the same course, maintaining a constant circulation.

Starting at the highest potential established by the dynamo, the potential gradient falls gently, owing to the slight consumption of volts required to overcome the small resistance of the main conductor. When it reaches the first lamp there is an abrupt fall, by the amount of the volts consumed in forcing the current through the high resistance of the lamp. Then follows a gentle grade to another abrupt fall at the next lamp; and so on to the last lamp, from which there is a last gentle grade back to the dynamo through the return wire.

When the same current passes through one lamp after another the lamps are said to be connected in series.

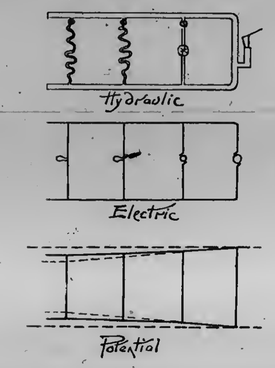
Turning to Diagram 2—the constant potential direct current system—the hydraulic diagram is an ordinary waterworks system, with the addition that all water used is discharged into a main return pipe which leads back to the pump, and from which the pump draws its supply.

The function of the pump is to maintain a constant difference of pressure between the mains. Each cross pipe from main to main takes whatever flow its frictional resistance will allow the main pressure to produce. And it is obvious that as more cross paths are opened, the increased work the dynamo must do, is due to the increased flow; the pressure remains constant.

In the electric diagram underneath, the high friction cross tubes are replaced by incandescent lamps, and the water motors by electric motors.

The potential diagram shows that the pressure in the mains cannot be quite constant, since there must be some fall of potential in the main conductors, and the amount of this fall is less when there are fewer lamps burning, i.e., when the total current is less. The potential gradient is

DIAGRAM II
Constant Potential Direct Current



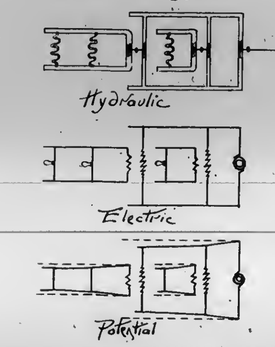
greatest near the dynamo where the conductor has to carry the total current, but the grade gets flatter and flatter as the current diminishes, by the amperes subtracted at each cross path. These potential gradients are repeated in the reverse order in the return wire.

The form of gradient drawn is that for a conductor of uniform size. But if the conductor is reduced at each cross path so that its area always bears the same proportion to the amperes carried, the potential gradient would be the same throughout, and a continuation of the first grade starting from the dynamo, as is indicated by dotted lines.

When lamps are connected side by side, so that each takes its own separate current, the lamps are said to be connected in parallel, or in multiple.

There remains the alternating current system shown by Diagram 3. The pump in Diagrams 1 and 2 produces a flow always in the same direction, representing a direct current of electricity. In Diagram 3 the pump is replaced by a movable piston in the main pipe, which being oscillated from one side to the other, produces a pressure first in one pipe and then in the other, with an accompanying back and forth flow which will vary in amount according to the number of cross paths open. This represents the primary circuit, to which the lamps are *not* connected. The object of an alternating system is to save in the cost of main conductors by transmitting power with a small current at a very high pressure. But for convenient and safe use, this power must be transformed into a larger current at a lower pressure, in a secondary circuit to which the lamps are connected. It is the peculiarity of the alternating system, that this can be done with very little loss and without any moving mechanism. The actual means by which this is effected in the "transformers" or "converters," are beyond the scope of this paper, but a simple mechanical contrivance in the hydraulic system will give us analogous results. A sliding piston in the small primary cross pipe and another piston in the large secondary pipe are connected by a bar pivoted in the middle, so that the two pistons oscillate together and move equal distances. If the area of the secondary piston is, say 10 times that of the primary, a secondary pressure 1-10 that of the primary will balance the the contrivance, whilst a secondary flow of 10 times the primary is produced by any oscillation.

DIAGRAM III
Alternating Current System



The electric diagram shows the alternator and primary circuit, feeding two separate secondary circuits through two transformers.

The potential diagram for both primary and secondaries is similar to diagram 2.

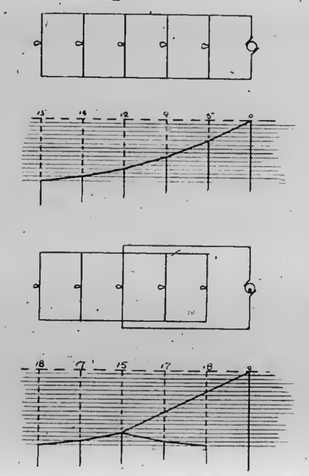
I may say parenthetically that the hydraulic analogy goes still further. The effects of the inertia of water represent excellently those of the electric quantity, self-induction, whilst, if the pipes are made elastic, the results would be very similar to those due to electric capacity. But as inductance and capacity are inappreciable in such work as an architect will ordinarily have to deal with, I have not considered them in this paper.

In wiring for incandescent lamps the object is to maintain as nearly as possible a constant difference of potential between the terminals of the lamps. But when, at different times, there are are at different points on the same line, different numbers of lamps burning, it is impossible that the volts at all points should be always the same. And the question is, what variation is permissible?

An incandescent lamp is simply a carbon wire of high resistance, which the current passing through it heats to incandescence. But the resistance of the carbon decreases as the temperature increases. Therefore a rise or fall in the volts causes more than a proportionate rise or fall in the amperes, and the consequent heat and temperature. Also, the light given out increases much more rapidly than the temperature. Roughly speaking a variation of 1% from the rated volts of the lamp, up or down causes a variation of 5% in the light. And it is informally agreed that 2% total variation in volts at any lamp constitutes good and satisfactory regulation. This variation is of course reckoned between the maximum and minimum load—not between full load and no load. If a group of lamps is fed by a wire direct from the constant volts of the source of supply, and the lamps in the group are always all turned on or off together, the drop of volts in the wire may be any amount, and yet because it will be always the same, there will be no variation in the volts when the lamps are burning.

But besides minimizing the variation in the volts at any one lamp, it is desirable that the lamps in the same building should all get about the same volts, so that the same class of lamp may be used interchangeably throughout the building. This is the object of the feeder system of indoor wiring, in which feeder wires carry the current to convenient points in the main wires to which the lamps are connected. Diagram 4 shows graphically the effect on the distribution of volts.

Diagram IV



The consolidation of experience in wiring, into practical rules, embodying safe practice as regards danger from fire, has been performed by the Fire Underwriters Associations. Their rules and regulations are published, and give in detail the minimum standard of safe wiring. The wiring must be at least as good as the rules prescribe, to avoid trouble with fire insurance. Among other things the rules prescribe the greatest amperes different sized wires may carry, and here is a point where they are not necessarily a sufficient standard to guide the architect. The Underwriter's aim is a single one, safety from fire; the architect has an additional aim, good and unvarying light; and our previous considerations concerning the resistance of wires, will show how these objects are not simultaneously attained.

The work spent in forcing a current through a wire generates heat in the wire, and the degree the temperature will rise to depends upon the relation between the rate at which the heat is generated and the rate at which it is got rid of. Now the rate at which heat is generated, is the rate at which work is spent in forcing the current through the resistance of the wire; i.e., it is the watts spent in the wire. And from Table 1, watts = (amperes)^2 × ohms. But we have seen that a long thick wire and a short thin wire may have exactly the same ohms resistance. With the same current the heat generated is the same in both. How about the resulting temperature? In the long wire the heat generated is spread over a greater length. The heat generated per foot run is less, and, the long wire being thicker, it also presents greater surface per foot run for cooling by radiation, convection or conduction. Obviously the short thin wire gets much the hotter. The safe carrying capacity of wires, both exposed and cased, laid down in the Underwriters' rules, is really a statement of the heat generated per foot that the wires can get rid of without becoming dangerously warm. This is independent of the length of the wire. The heat generated per foot remains the same, but the longer the wire, the greater the total heat and the greater the total volts lost in forcing the same amperes through the resistance of the greater length. But the total drop in volts is what the architect must limit in order to get good and steady light. He must therefore be guided by the total resistance, and the ampere capacity of the Underwriters' rules is useful to him only as setting the inferior limit to which he may reduce the size of the wires.

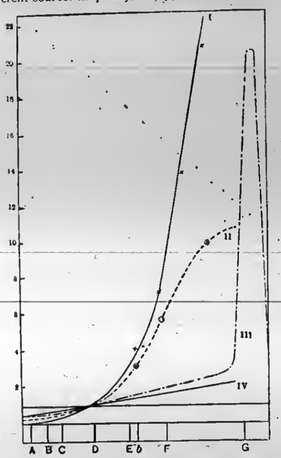
With regard to the different classes of wiring—exposed wiring on cleats or knobs is best for factories, but for domestic work it is only suitable in stores or houses where hanging kerosene lamps, or exposed gas pipes

stapled to the walls and ceilings, would be the alternatives. What is called concealed work, in which rubber covered wires are run between floor and ceiling, and brought out only where brackets or hanging fixtures are to be placed, is probably the most suitable for the ordinary run of dwellings. Where once in, there is little liability of its being disturbed. But in larger buildings, warehouses, stores and such like, where there are likely to be changes in partitioning off the space, and in the distribution of the lights, to suit different tenants, or the same tenant at different times, wires run in mouldings are by far the most convenient. They are not only most readily accessible for changes of wiring, but the wiring is much less liable to damage by workmen in other trades making repairs. The principal objection is the unsightliness of lines of mouldings straggling all over the ceiling to wherever a lamp is needed. But moulding work has frequently many advantages of convenience to recommend it. Architects, I believe, are always looking for a "motive" in design. Mouldings can be made of any section, and perhaps they might be used to panel off the ceiling in some decorative pattern, suitable to any probable distribution of lights, giving a wide choice of paths for wiring and points for outlets. But this touches the artistic side of architecture, which is beyond my province. The best class of wiring is interior conduit work, in which buildings are piped with strong non-metallic, waterproof and poorly combustible tubing, and wires subsequently drawn into. This is particularly suitable to such work as the best class of office buildings. And where it would be too expensive to carry throughout a building, it may sometimes be used for the main lines to centres of distribution

When incandescent electric lights were first introduced they were distributed on wall brackets and hanging fixtures in the same manner as gas jets, as if this were the natural arrangement of lights, instead of having originated in the necessity of keeping gas jets within reach for ease in lighting, and in keeping them away from walls and ceilings for fear of fire. This force of habit for some time prevented, and in a measure still prevents full advantage being taken of the possibilities offered by electric lights for getting better illumination with the same amount of light. For a desk light or a reading light we cannot do better than replace the shaded oil lamp or gas drop light by a shaded electric lamp, but for the general illumination of a room the incandescent light can, in general, do much better. The illumination we perceive depends not only on the amount of light reflected from an object, but also on the amount of the reflected light the eye takes in, and with lights a little above the level of the eye, we are always partially dazzled by them, and our perception of surrounding objects is indistinct compared with what it would be if the lights were out of sight. To get the best illumination for the quantity of light, a room should be lighted as a picture is lighted for exhibition. Electric lamps high up near the ceiling remove the dazzling effect and at the same time give a more generally diffused light, especially if there are light tinted walls and ceilings to reflect the light without much loss.

For lighting large rooms, arc lamps are used to a considerable extent on the continent of Europe, constructed so that they throw all their light on a white or light tinted ceiling, the room being thus lighted entirely by reflection from the ceiling. The result is a diffused light as shadowless as diffused daylight.

Now with regard to uses of arc and incandescent lights. Diagram V is copied from one by Prof. Nichols, of Cornell, embodying the results of experiments made by him, and is instructive in illustrating the difference of light from different sources in quality, as opposed to quantity.



This diagram represents the brightness of different parts of the spectra of the electric arc, clear daylight and clouded daylight, in comparison with the same colours in the spectrum of an incandescent lamp. The brightness of the latter is taken as the standard in all parts of the spectrum, and is represented in the diagram by the horizontal line at the height 1. The other spectra are reduced to the same brightness at the yellow line D, and their brightness in other regions of the spectrum is shown by curves.

Curve I represents daylight on a cloudless summer day.

Curve II represents daylight under a densely clouded sky.

Curve III shows the light from an electric arc.

Curve IV is from the lime light.

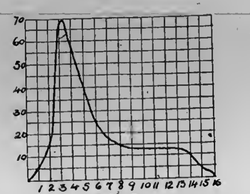
The abrupt rise and almost immediate descent again of curve III indicates a narrow but very bright band of light in the violet end of the arc spectrum, which accounts for the value of the arc light in photography, and also explains the predominant bluish tinge of its light.

The curves show how far all artificial illuminants fall short of equalling the quality of clear daylight, which latter must always be our standard of perfect white light. Even the light of a very dull day is a better all round light than an arc light or lime light of equal general brightness.

Lights are usually rated by candle power, and this is gauged by the relative blackness of shadows thrown on a white ground. Candle power therefore merely measures the ability to distinguish between black and white. For this purpose the yellow rays are much the most effective; but the blue and violet rays are the most useful for showing the distinction between colors, that is, for bringing out the colors of natural objects. And this being so, the curves show that the incandescent lamp gives us the most of that kind of light wanted, for reading or writing, whilst the arc light gives a closer approach to the effect of daylight upon colors. In addition to positive utility, the feeling of suitability has a value. The incandescent lamp, with its warm yellowish red glow, gives a cheerful and cosy air to a small room, where an arc lamp would be simply garish. In a large hall or store, to which the idea of cosiness is inappropriate, the same light that makes a small room cheerful may give only an impression of dullness, whilst the arc light would give an agreeable effect of brilliancy. Of two large stores side by side, one lighted by arcs and the other by incandescents, the arc lit store has in general a more attractive air of being brilliantly lighted, although, measured by candle power, its actual illumination may be decidedly inferior.

Diagram VI is a curve of current consumed in one trip of an electric elevator. The time in seconds is measured horizontally, and the amperes vertically. This is a diagram from an actual elevator, running 250 feet per minute in a three-storey building. I have taken several such diagrams from different elevators and they all have the same general form as the one shown. I have chosen this one of an elevator having a short run, in order to better bring out the effect on the current consumption of frequent stops. The peak at the beginning of the curve shows the large current required to start the car and accelerate it to full speed, in comparison with the small current needed—from 7th to 14th, second in diagram—to keep the car in motion after speed has been attained. Nevertheless, even in this unfavorable case, the curve shows the very small cost of power per trip.

Diagram VI



Area of Curve 500 Ampere seconds at 250 Volts

Price of Power 6¢ per H.P. Hour

$\frac{250 \times 300 \times 6}{746 \times 60 \times 60} = \frac{1}{6}$ (nearly)

Power Cost 1/6¢ per trip

For the diagram given the cost is only ½ cents per full trip one way, at the rate charged in Toronto for very intermittent use of current, which is 50% higher than the regular Toronto meter rate for power supplied to an elevator in constant use.

Hitherto the application of electricity to architecture has owed little to architects. Trade competition has forced in electric power to take the place of power from other sources which had been already applied to elevators, pumps, ventilating fans, &c.; but beyond this little has been done. The convenience of electric power has certainly led to the extension of mechanical ventilation, with its steady displacement of a fixed volume of air per minute, independent of the degree of dryness or temperature which makes ventilation by natural draught so variable. In ventilation architects have been fairly quick to utilize the opportunity afforded them. But in the larger problems of architecture, the possibilities of applying electricity seem to have received little or no attention. An illustration of what I mean is what might conceivably, though not probably, be the effect of cheap electric power in modifying the design of dwelling houses. If it were desirable to use elevators it would not be very difficult to devise perfectly safe methods of operating them without trained attendance, and a constantly used elevator would have almost as great an effect in modifying house planning as the substitution of stairs for ladders. Supposing such a use of elevators were practicable; whether it would be desirable, whether it would really add to the comforts and conveniences of life, nobody can say so well as the architect, who alone is trained to appreciate at their proper value all points bearing on such a question. And that is the point I wish to bring out by the illustration. Whether in the future electricity is to play any part in modifying architecture; whether it be of any real assistance to the architect in dealing with the particular problems of his profession, depends principally on the architect himself. The electrical engineer must co-operate in devising working details, but if the applications of electricity to architecture are ever to be more than superficial, the initiative must come from within, not from without.

The following are the officers elect for 1895: Board of Directors—George Oakley, president; John Aldridge, 1st vice-president; Wm. Park, 2nd vice-president; David Williams, treasurer; Wm. Peats, Thos. Cannon, Jr., James Crang, Wm. Booth, Henry Martin, Fred'k. Wakefield, Henry Lucas, James Isaac.

THE WEATHERING OF BUILDING STONE.*

The slow decay of everything exposed to the weather has become a proverb, and from the earliest times men have moralized on the "gnawing tooth of time," as though time were some relentless monster devouring slowly man and all his products; but of late years geologists have begun to make some enquiries as to the monster, and to find out somewhat exactly what time's gnawing tooth really is. The question is one of great importance to the student of geology, for the weathering and wearing away of the solid rock and the building up of its materials in new places are among the most significant factors in the ceaseless round of change by which mountains and valleys and plains are carved and re-modelled on the earth's surface. To the geologist no structure is permanent, the "everlasting hills" do not last forever; in fact the destructive forces are most actively at work where the mountain lifts its head so boldly, as if to defy the elements.

The "tooth of time," when examined a little carefully, turns out, as so many bugbears do, to consist of very simple and innocent elements. Air, water, change of temperature; these three factors alone or in combination, with traces of a few common acids, are the effective forces in the weathering of the rocks of the geologist and of the stone of the architect. The effects produced by these agencies may be purely mechanical, or purely chemical, or more often a mixture of both.

In climates like our own, where the extremes of heat and cold may run from 100° in summer to 15° or 20° below zero in winter, the effect of mere change of temperature may be important in its disintegrating action on building stone. The rise of temperature, when sunshine falls upon the wall of a building, is imparted to the outer layers of particles of the blocks of building stone and expands them, granite having been found to expand .000004825 inch per foot for each degree Fahrenheit, marble .000005668, sandstone .000009532.

Since stone is a poor conductor of heat the surface will expand more rapidly than the interior, and there will be a tendency to form minute cracks and to chip off the surface of the stone. It is said that the south side of stone buildings, exposed to great changes by the coming and going of sunshine, begins to roughen and disintegrate sooner than the north side in New York and other American cities. The ill effects of change of temperature will, of course, be more apparent in the case of stone like granite, made up of minerals differing in their rate of expansion by heat. This is most strikingly shown in case of fire, when granite, though stronger and more compact than sandstone or limestone under ordinary circumstances, crumbles far more easily in the intense heat.

Another injurious effect of change of temperature is to be found in the loosening of the joints between the blocks of stone in a building. Supposing the stone to have been laid in summer, all the blocks will occupy less space in the cold of winter, and minute fissures will tend to form in the cement or between it and the stone. These fissures admit water and make the starting point for other changes.

Change of temperature alone is, however, not a rapid agent in disintegration. It is the presence of water that gives it efficiency as a destroyer in climates like ours in winter where freezing and thawing occur in rapid succession. When water freezes it expands with an almost irresistible force, which has been estimated at 138 tons per square foot at 2° below freezing, and is quite sufficient to rend the strongest rock. All the tiny fissures and crevices of a block of building stone exposed to rain or melting snow become filled with water, which may afterwards freeze, wedging off fragments. Another thaw followed by another frost pushes the parts still farther asunder until the stone splits and crumbles. Stone buildings of many kinds illustrate this action on the sides exposed to storms. It is very well seen on many New York brown stone houses, where the porous Connecticut sandstone has been sawn and set on its edge, and after a few years scales so as to be quite unsightly.

The action of frost depends very largely on the porosity of any stone exposed to its influence. A compact massive stone like granite or many limestones is little affected, while porous limestones, and especially sandstones, are very quickly injured in exposed positions. In this respect the capacity of a stone to absorb water is of great importance, and one may say with Sterry Hunt that, other things being equal, "the value of a stone for building purposes is inversely as its porosity or absorbing power." N. H. Winchell gives in a report of the Geological and Natural History of Michigan (Vol. I, p. 197, etc.), a table showing that massive crystalline stones, like granites, syenites and gabbros, absorb very little water, generally much less than one per cent.; dolomites absorb a little more, and dolomitic limestones still more, up to 3 or 4 per cent. Limestones absorb rather less, while sandstones absorb very much more, the lowest amount in his table being three per cent., and the highest 12.69 per cent. Sterry Hunt found that Potsdam sandstones from Canada absorbed from 0.50 to 3.26 per cent., Medina sandstones from Canada 3.31 to 4.04 per cent., and subcarboniferous sandstone from Ohio 9.59 to 10.22 per cent. Silurian limestones and dolomites from Canada examined by him absorbed from 0.11 to 5.55, while Tertiary limestones from Caen, France, absorbed from 15 to 16.05 per cent. of moisture.

As a general rule a stone absorbing 10 per cent. of water crumbles rapidly in our winters, and should not be employed where carving or a fine finish of any kind is exposed to the weather.

Thus far the purely mechanical side of weathering has been discussed. Let us now turn to the chemical side. The air consists of about four parts of nitrogen and one of oxygen, with varying amounts of watery vapor, a little carbonic acid and traces of ammonia and other nitrogen compounds. In cities it may also carry soot and traces of some common chemical compounds, such as sulphur dioxide, sulphurous and sulphuric acids, hydrochloric acid, nitrous and nitric acids.

Rain water is more or less strongly charged with oxygen, carbonic acid and other substances found in the air. The nitrogen of the air is inert and the oxygen and other substances are active only in the presence of water, so that very dry air has little or no effect in weathering. In very dry climates like that of Egypt monuments of stone may be ground off by driving desert sand acting as a sand blast, but are scarcely affected in other respects after 4000 or 6000 years exposure to the weather. How differently a damp climate affects the same stone may be seen only too well in the Egyptian obelisks transported to London, Paris and New York. It is well known that in the last city the granite scaled so rapidly that the obelisk had to be coated with paraffine to preserve it at all.

The action of oxygen as a weathering agent is important in respect to a few minerals only. Certain sulphides, especially the brassy yellow mineral iron pyrites, are changed by oxygen in the presence of moisture into sulphates and finally into oxides. Granites, marbles and other crystalline rocks containing these minerals, may be weakened by their weathering out, and are stained an ugly brown by the hydrous oxide formed, so as to be quite disfigured. This change is less important in the sandstones, though even then the change of colors may be disagreeable. Many stones used in the Parliament Buildings at Ottawa illustrate this, the dark brown smear having sometimes run down on to the blocks below. Stones rich in magnetite, such as diabase, sometimes used as black granite, may be noted on in a different way. The mineral magnetite consists of the sesquioxide of iron combined with the monoxide. The latter portion may weather into hydrous sesquioxide, giving brown stains, and sometimes causing the rock to crumble. A similar effect, though less important, has been observed in some massive rocks containing large amounts of silicates rich in iron, hornblende or augite.

Water charged with carbonic acid is a very efficient weathering agent, and has some action on most minerals, except quartz. In the granite of the Thousand Islands large blocks of quartzite are sometimes found, and as a rule the quartzite projects sharply an inch or so above the granite, showing the amount of weathering and degradation since the time some thousands of years ago when all was planed smooth by glaciers.

In the case of granite and other massive crystalline rocks this weathering consists in the change of the felspar into clayey substances and of the mica and hornblende into impure clay, oxides of iron, etc. The quartz grains are loosened in this way and are washed off by rain action, leaving fresh surfaces exposed. Without the help of frost it is probable that this variety of weathering would go on very slowly. Granite monuments in our cemeteries seem but little affected even after standing a number of years, though they gradually lose their polish and grow rough.

Limestones are more easily attacked. If pure they are slowly dissolved, but keep a tolerably smooth surface. If impure, as they generally are, the particles of sand and clay are insoluble and form a crust on the surface. With this the soot of city atmospheres combines to change the original color into a dingy black. Limestones with large fossils soon become unsightly on dressed surfaces from the projection of the fossils. Marbles or crystalline limestones are very readily acted on. A study of marble tombstones in our cemeteries shows that even a few years exposure removes the polish, except on parts that are protected. Every marble slab which I have examined, bearing a date of twenty years or more ago, has completely lost its polish on all exposed parts, has turned grey in color and is so friable that one can easily rub off particles with the finger. It is quite evident that marble is entirely unsuited for outdoor use in the climate of Toronto.

Sandstones differ greatly among themselves in their liability to weather, hard quartzitic ones being almost unattacked, while porous, loose textured sandstones crumble sometimes very rapidly. These differences depend chiefly on the character and amount of the cement which holds the particles together. A clayey cement is the worst, since it readily absorbs moisture and is crumbled by the action of frost. Such sandstones are seductively easy to work, so that builders are tempted to use them for carvings, but often the storms of a single winter will round the edges and spoil the sharpness of such carvings, particularly on exposed corners of buildings.

A calcareous or lime cement, though better than clay, is comparatively easily dissolved by rain water charged with carbonic acid, and still more easily by water containing traces of sulphurous or sulphuric acid, such as may frequently be found in the air of cities. Carbonate of iron is another, though rarer cement, which is easily soluble. The red anhydrous oxide of iron resists solution very well; the brown hydrous is less resistant. The most permanent cement of all is a siliceous one, which is practically unaffected by rain charged with any ordinary solvent; but unluckily such sandstones are so hard to work and usually of such poor colors that builders rarely employ them.

A rather fine grained grey sandstone frequently used in our cemeteries, has turned darker grey, but resists weathering often admirably. Horizontal slabs fifty years old are not at all friable and still retain their inscriptions, though somewhat encrusted with dirt and lichens. A yellowish sandstone has not stood as well, and after thirty-five years in one instance has weathered so as to be quite illegible.

The presence of clay spots in sandstones is most injurious to the appearance, since they weather out and leave ugly holes, sometimes not standing even a single winter. The filling of the holes with powdered sandstone and shellac renders the stone presentable, but only for a short time. Still worse is the presence of clayey layers between the laminae either of sandstone or limestone. The clay rapidly weathers out, spoiling the dressed face of the stone and in time weakening the whole wall.

The hardening of certain limestones and sandstones after quarrying is an interesting effect of the action of the air, though not properly included under weathering. It appears to be due to the drying out of the quarry water with which the stone was soaked. As it drys out, all the substances which it held in solution, such as lime and silica, are deposited, hardening the surface of the block. If once this hardened skin is removed, however, no amount of wetting with pure water will renew it.

Thus far we have considered the action of the weather in decomposing and dissolving part or all of the constituents of a building stone, injuring its strength and durability; but there is another action of some importance to the architect as an artist, that is the slow change of color which most varieties of stone undergo after taking their place in a building. This may be called the mellowing touch of time as contrasted with his gnawing tooth, and from the artistic side an architect's work, like a rich wine, may ripen and improve with years.

Most of these color changes are the result of slow oxidation. Some dark grey or bluish limestones, like those of Kingston, contain bituminous matter from the multitude of fossil organisms that died to form these beds of rock. This color is slowly lost by oxidation and the surface of the stone gradually reaches the true color of the limestone, a pale grey, sometimes even suggesting marble. As a general rule such changes of color are due to oxidation of iron compounds from the monoxide, which is green or black as a rule, to the sesquioxide, which is yellow or brown or red. The general effect then is to change the color from cool greenish greys to warmer yellows or browns. An old marble statue, cold white in the beginning, becomes yellowed like old ivory with the lapse of time; but this change may be due partly to the action of dust and soot in cities. Many whitish or grey limestones yellow in a somewhat similar way. Grey or greenish sandstones generally take on a yellow or brown tone in time. In many cases this change of color is a distinct improvement, especially where stones of different colors which do not quite harmonize have been used together.

Of course in cities burning much soft coal, color is of no importance, since all colors are presently shrouded in an impartial pall of sooty grey or dingy black.

In towns burning mostly hard coal, like our own Toronto, with its usually clear skies and clean atmosphere, the color scheme and the changes which time will give rise to should be carefully considered, more so than they are at present.

In choosing a building stone which has not been thoroughly tested by use one may very easily make mistakes. The color, the texture, the power to resist crushing strain, as the stone comes from the quarry, may all be greatly modified by weathering. The amount of moisture which the stone will absorb, the chemical constitution and the mineral composition, as shown under the microscope, all afford data by which to judge of its lasting qualities; but perhaps the best test of all is to examine the neighborhood of the quarry and see what effect weathering has had upon loose blocks or exposed ledges of similar stone. In any case, architects in choosing stone for buildings intended to be of a lasting and monumental character, should take every means possible to determine the durability of the material they are working with.

*Paper by Prof. Coleman, School of Practical Science, Toronto, read at the fifth annual convention of the Ontario Association of Architects.

NO TEUTONIC ART.

THE art we call Teutonic is really Byzantine. The tribes which were planted on the various frontiers of the empire, and were largely in its service, were all directly indebted to Byzantium for their art. Hence while we find the same art, with slight local differences, among the Goths of the Crimea, the Lombards in Italy, the Burgundians in Austria and Switzerland, the Alemani on the Rhine, the Merovingians in Gaul, the Angles and Saxons in Britain, the Visigoths in Spain, the Vandals in Africa, and the early Scandinavians in Denmark and Scandinavia. The cloissoné jewelry, the interlaced dragon patterns, etc., all of which have such a common likeness, have an equally common likeness with the work which we can trace to the Queen of Bosporus, and, as Lindenschmidt was never tired of preaching, there is no Teutonic art. The art of all the Teutonic tribes who founded the modern States of Europe was in reality the art of Byzantium, and this was so in later times also. The art of the Carlovingian Empire, and of the later Anglo-Saxons, was the art of the exarchate of Ravenna, just as the art of Southeastern Europe, as preserved in the churches of Kief, was the direct daughter of Constantinople.—Sir Henry Howarth, in The Antiquary.

So far from stencilled effects in wallpaper losing their popularity they are unquestionably gaining ground, and those who admire them most are those whose taste is best cultivated. The design of a wallpaper based on stencils is as artistic and effective as any, provided, of course, that proper care is taken in the selection of colours.

A writer on painting states that the ochre best suited for the purposes of the house-painter will show an analysis about as follows: Hydrated oxide of iron 45 per cent., Silica 35 per cent., Alumina 20 per cent.

Yellow is the Chinese imperial color, not to be desecrated by common use. Imperial buildings are roofed with yellow tiles. The Pekin Gazette is issued in a yellow cover; the national flag has a yellow ground; and the Emperor's own robe is of yellow silk, embroideerd with a gold five-clawed dragon.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 3. MARCH, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS, AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2259.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 10th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this Journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

THE building season of 1895, about to open, promises to be one of much greater activity in Ontario at least than that of 1894. The recent extensive fires will create a considerable local demand for labor and material in Toronto. This will apply in a lesser degree to London, Halifax and other places. The number and extent of new building enterprises seem also to be on a more promising scale than last year. We therefore bespeak for architects, builders and supply firms the enjoyment of more satisfactory conditions than those which have fallen to their lot of late.

EVER since the Ontario Legislative buildings rose to public view, there has been but one opinion expressed by capable judges concerning their outward appearance, viz., that it displays not a single interesting feature. Occupation of the legislative chamber has demonstrated the fact that its acoustic properties are also of the worst possible character. A daily paper affirms that "The members can't hear each other on the floor of the House, the press is at a great disadvantage for the same reason, while as far as the visitors in the galleries are concerned they might as well be at a pantomime." It seems pertinent to enquire what advantage has accrued to any Canadian interest from the employment of an American architect in the erection of these buildings over the heads of capable home talent.

IN the paper on "English Methods," by Mr. Frank Baker, A.R.I.B.A., presented to the O.A.A. at its last meeting and printed in the present number, the author says: "The system of carrying all soil pipes on the outside of outside walls is a good one, and though it is said that our severe climate prevents us from adopting this principle here, it is likely that we will come to it in some form eventually. Perhaps a well ventilated brick flue might be constructed to contain these pipes, but something ought to be done to get them outside of the building." We are heartily in accord with this view. In spite of all the precautions that can be exercised, there exists an element of danger to the inmates of a dwelling in which the drainage system forms part of the interior construction of the building. The method of carrying drains outside the walls of dwellings has been followed to a considerable degree of late, and it would add materially to the security of human life if means could be devised whereby the soil pipe would likewise be relegated to the outside of the building.

ABOUT two years ago the Council of London, Eng., decided to abandon the system of submitting to tender the public works of the municipality, and to have them carried out under the immediate supervision of its own officials. By this means it was claimed there would be saved to the citizens the contractors' enormous profits. The experiment, which has been watched with world-wide interest by municipal bodies and public contractors, seems to have proved a dismal failure. In the case of several costly public improvements carried out under the new method, the cost is shown to have exceeded the estimate of the city officials by 20 per cent., or in round figures £7,200. A quarter of a million pounds has been invested in buildings and contracting plant, which will be practically lost should a return

to the former system be found advisable, as seems probable. Sir John Hutton, chairman of the Works Department, expresses the opinion that the workmen may not be disposed to do as good work for the Council as for a contractor. It will be remembered that not long ago the City Council of Toronto tried the same experiment, and with the same result. In both cases, the desire to curry favor with the trades unions seems to have been the actuating motive.

A RECENT and instructive experience with a steam heating plant is reported in connection with one of the Toronto public school buildings. Last summer the Bolton avenue school, a two-storey building, was enlarged to contain sixteen class rooms, instead of twelve. This was done by adding a third storey, making an increase of fifty per cent. in the space to be heated. The apparatus formerly consisted of one boiler and plain coils of steam pipes—the usual pressure of steam running at six to eight pounds gauge—and all worked well. For the new storey the old mains and returns were enlarged where necessary, and new extensions put in, with cast iron radiators. With the advent of cold weather it was found impossible to make the apparatus do its work, as the water backed out of the boiler into the returns before sufficient pressure could be obtained to make a circulation. Up to this time there had never been a check valve on the return connection with the boiler, and Mr. Bishop, Superintendent of Buildings and architect for the School Board, was of the opinion that to provide one would overcome the difficulty. The contractor for alterations to the plant and others having extended experience with steam apparatus differed from him, thinking this would have no appreciable effect and that another boiler of the same capacity as the one in use would be found necessary. The check valve was put in at a cost of about twenty-five dollars, and the system worked as perfectly as ever, satisfactorily warming the whole building even during the extremely cold weather which prevailed at times during the past winter. The amount of fuel consumed is about fifteen per cent. more than formerly, with a corresponding increase in the steam pressure required. An additional boiler would have cost nearly one thousand dollars, with an annual cost of at least one hundred dollars more for fuel than the present arrangement. In the building referred to there are 268,000 cubic feet of space with 2,200 sq. feet of window glass. The heating is entirely by direct radiation and the boiler heating surface is one-tenth the radiating surface, a proportion allowed for ordinary buildings by Baldwin, the eminent authority on steam heating. These facts show a rather wide difference of opinion among people who ought to know the requirements, and that the subject of apparatus for heating or ventilating is one with which architects should be thoroughly familiar.

BUILDING CONSTRUCTION IN ITS RELATION TO FIRE PROTECTION.

THE large fire which caused such destruction to buildings in one of the principal parts of Toronto last month, made reasonably clear that the series of conflagrations by which Toronto has been visited of late were due to incendiarism. It can hardly be conceived in the light of the immunity which the city enjoyed for so many years, that three such conflagrations should take place within so short a period from accidental causes. It has been the subject of comment that in each instance the fires originated in buildings situated in the very heart of the business district of the city, where there was a reasonable certainty of their being rebuilt. It is to be hoped that the reward of $1,000 offered by the Underwriters' Association for the conviction of the incendiaries will have the desired result.

The rapid destruction of Mr. Robert Simpson's new departmental store building, an illustration of which appeared in the January number of the CANADIAN ARCHITECT AND BUILDER, and which was among the first of the buildings erected on the modern iron construction principle, not only demonstrated the insufficiency of the city's fire equipment, but what is more important, the fact, that so long as the prevailing methods of building are allowed to continue, the most effective fire extinguishing appliances will be of little avail in preventing the spread of fire when once it shall have obtained hold upon a building. If a merchant wants a building put up with the greatest amount of floor space and with street fronts almost entirely of plate glass, his architect may advise him of the danger to which it will be exposed from fire, and that it will also be a menace to the safety of surrounding buildings, but if the proprietor refuse to go to the expense of making the building fire-proof and be willing to assume the risk of having it destroyed, the architect can do no other than carry out his wishes. It is here that the law should step in and prevent the erection of structures of such a character. Since the recent fire, a clause has been discovered in the existing building by-law of the city, limiting the floor areas of buildings and providing other safeguards against fire. Strange to say, this clause has been more honoured in the breach than in the observance. It reads as follows :

"No block of warehouses or storehouses or other buildings (except churches, public halls and opera houses) shall contain more than forty squares of building on the ground floor thereof, including internal and external and half the party walls belonging thereto, unless such building be separated and divided by party walls into divisions of not more than forty squares of building as aforesaid, unless the permission of the City Council shall be first obtained. No block of warehouse or other buildings shall communicate with any other block of warehouses or other buildings through a party wall, nor shall any stable communicate with any other stable through a party wall, unless the door case and sill of every such communication be of stone or wood covered with tin, and unless there be to every such communication a door of two thicknesses of wood covered on both sides with tin. No timber bond or lintel shall be laid into the brick work of any wall in any such building nearer than eighteen inches to the opening of such communication, unless the door case and sill of every such communication be of stone or of wood cased with tin."

The committee, consisting of Messrs. H. B. Gordon, W. L. Symons, W. R. Gregg, Edmund Burke, D. B. Dick, B. Jarvis, J. A. Pearson, Mark Hall, E. J. Lennox and Geo. Miller, appointed by the Ontario Association of Architects to recommend to the City Council needed amendments to the city building by-law, have lost no time in dealing with the subject. Since their appointment the committee have held eight meetings, at which the building ordinaces of London, Eng., New York, Chicago, St. Louis and a number of other cities, have been carefully considered, together with other data bearing on the subject in hand. As the result of their deliberations the committee have framed a by-law which will be recommended to the City Council at an early date. In view, however, of the unusual circumstances at present prevailing in the city, and the urgent necessity for immediate legislation to prevent the erection of buildings constructed in a manner similar to those recently destroyed, the committee have recommended that the following provisions be at once incorporated into the existing by-law :

FIRE-PROOF BUILDINGS.—Every building hereafter erected, which belongs to the public building class or the hotel class, the highest occupied floor of which exceeds 50 feet in height from the average ground line ; and every building hereafter erected belonging to any other class, the highest occupied floor of which exceeds 70 feet in height from the average ground line, shall be built fire-proof ; that is to say :

It shall be constructed with walls of brick, stone or terra-cotta, or other hard, incombustible materials. No wooden beams, lintels, bond timber or wood strips shall be built in walls.

The floors and roofs shall be constructed of brick or terra-cotta arches or other hard, incombustible material, and the supporting beams shall be of steel or iron, all properly cased with non-combustible material.

The stairs and staircase landings shall be built of hard, incombustible materials.

No woodwork or other inflammable material shall be used, excepting the floor boards, the doors and windows and their frames, and the trims, casings and interior finish, when filled solid at the back with fire-proof material. The exposed parts of all constructional steel and iron work, supporting walls, floors, roof or stairs, shall be efficiently protected with at least 2 inches of porous terra-cotta ; or, where such is not feasible, with wire lath and plastering of sufficient thickness.

No existing non-fire-proof building shall be converted to the purposes of a building of the public building or hotel classes, the highest occupied floor of which exceeds 50 feet from the average ground line, and no existing non-fireproof building shall be increased in height to exceed the limits set forth in this section for new buildings of the same class.

But nothing in this section shall prevent the erection of what are known as grain elevators as usual y constructed, provided they are erected on the water front in isolated localities, and under such conditions as the Inspector of Buildings may deem prudent.

ELEVATORS.—Where elevators are enclosed in shafts, all the enclosing walls must be built of brick or terra-cotta or other incombustible material.

In all buildings of the manufactory class that are more than 2 stories in height above basement, and in all buildings of the store and warehouse class that are more than 3 stories in height above basement, the elevators must be enclosed in shafts built of brick or terra-cotta, and extending at least 3 feet above roof, and covered with a light glass sky light or easily broken covering ; and all the doorways opening into such shafts shall be closed by iron doors, or else by doors of two thicknesses of solid boards covered all over with asbestos and sheet metal.

Where elevator shafts cannot conveniently run to top story and from thence out to roof, the top of shaft must be covered with a fire-proof ceiling.

Where elevators are open, the guide posts and corner posts must be of iron, and any inclosing screens must be of incombustible material. No woodwork of any kind, other than strips on cage guide posts, shall be carried from floor to floor.

FLOOR AREA.—No building hereafter erected (except public audience rooms) shall have on any floor thereof more than 4,000 square feet of floor area undivided by division walls. Nor shall the undivided floor area of any floor in any existing building (except public audience rooms) be increased so as to contain more than 4,000 square feet.

Division walls to divide the floor area of a building into spaces of not more than 4,000 square feet must be of stone, brick or terra-cotta.

Door or other openings through division walls must not exceed in their united width one-third the length of wall.

All openings through division or party walls shall have tight-fitting doors and frames of iron ; or else, if of wood, constructed of two thicknesses of solid boards, and covered with asbestos and sheet metal.

Each section of floor area divided from the rest of building by division walls and fire-resisting doors shall have a separate stair and exit to street.

All fire-proof buildings, built as described for fire-proof buildings under section ..... of this by-law, shall be exempt from the restrictions as to floor area.

PROTECTING STRUCTURAL IRON WORK.—All metal columns and beams supporting walls, except first floor and basement columns on street fronts shall be efficiently protected by non-combustible materials.

There is a misconception on the part of the public as to what constitutes a fire-proof building. The opinion is held that buildings such as the Simpson and McKinnon buildings recently destroyed, constructed with iron supports, were intended to be fire-proof. This is altogether an error. It was perfectly well understood by the architects of these buildings that the safety of these structures was in no way enhanced, but rather endangered, by the use of an unprotected iron frame work. The advantage sought to be gained by the use of this method of construction was rather in the direction of securing larger floor and light areas. As was pointed out in an article on this subject in the CANADIAN ARCHITECT AND BUILDER for January, iron should not be used for the support of a building unless covered with fire proof material such as porous terra-cotta, and it is hoped that the proposed new building ordinance of the city will render this imperative.

A provision which would to a considerable extent enhance the safety of buildings from injury by fire originating on adjoining premises, would be one which would compel the owners of business buildings to protect with iron shutters the windows in the rear walls abutting on adjoining property. Two of the greatest sources of danger are windows and elevator shafts. The windows are broken by the heat, thus setting in motion currents of air by which the flames from burning buildings adjoining are sucked in through the openings, carrying with them destruction to the interior of the building. It is too much to require owners of office and other business buildings to disfigure them by placing iron shutters on the windows of the principal street elevations, but no such objection could be urged as regards the protection of windows on rear walls.

Yet another valuable protection, to our mind, would be moveable iron floors in elevator shafts, which should be employed at night to shut off each flat of the building. One of the recommendations of the committee of the O. A. A. is, that such shafts should be lined with fire-proof material and should have fire-proof doors at the entrances on each flat ; that the shaft should extend three feet above the roof and be covered with glass, which would be easily broken by heat. This provision is a wise one as far as it goes, its object being to confine the fire to the shaft and prevent its spread laterally throughout the building. There is danger, however, that combustible material would be carried through the top of the shaft to the roof of the building and to building's adjoining. Such a provision as we have mentioned would act as a more complete safeguard, tending to prevent the fire from extending beyond a single flat where, thus confined, it could effectually be dealt with by the firemen.

Some attention should be given to the construction of floors in a manner that would offer greater resistance to fire. The plastering of ceilings is quite a protection to the under side of the floor, and if floors were lined with asbestos or laid in mortar, a much longer time would be required for them to burn out.

ONTARIO LAND SURVEYORS.

THE annual meeting of the Ontario Land Surveyors' Association held in Toronto a fortnight ago, was one of much interest. Papers were read on "Good Streets," by H. J. Brown, of Berlin, Ont ; "Highway Bridges," by Peter S. Gibson, of Willowdale, Ont., and on "Mining," by J. D. Evans, of Trenton, Ont. The proceedings terminated as usual with a banquet. The following gentlemen were nominated for the Council of Management, the election to be by ballot of all the members of the society in the Province :—P. S. Gibson, Willowdale ; Jas. Dickson, Reeve of Fenelon Falls ; A. Nieven, F. B. Speight, Toronto ; Geo. Ross, Welland ; J. D. Evans, Trenton ; Wm. M. Davis, Woodstock ; Harry Brown, Toronto ; T. H. Jones, Brantford, and F. S. Foster, Toronto ; Auditors, H. B. Proudfoot and W. A. Brown, Toronto.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

MASTER PLUMBERS' ASSOCIATION OF MONTREAL.

THE Master Plumbers' Association held their first annual banquet at the Queen's Hotel on Monday, the 25th February. Over a hundred and fifty guests sat down at the tables, and amongst those who occupied seats of honor on the right and left of the President, Mr. Joseph Lamarche, were Acting Mayor Leclerc ; Aldermen Beausoleil, Hurtubise, Grothé and Jacques ; ex-Alderman Clendinneng ; Mr. J. E. Doré, Sanitary Engineer ; Messrs. T. J. Clark, Jas. Robertson, W. Robertson and Lieut.-Col. Massey. The first toast proposed by the President was that of Her Majesty the Queen, after which Mr. John Date proposed The Right Hon. the Earl of Aberdeen. The next, The President of the United States, was responded to by ex-Alderman Clendinneng.

The corporation of Montreal having been honored, Alderman Beausoleil, the Chairman of the Health Committee, was the first to respond. "If plumbing work is well done," he said, "it is a public boon, but if badly done it is a public menace." As member of the Health Committee he had great pleasure in assisting at the passage of the Sanitary By-Law recently passed.

Acting Mayor Leclerc addressed a few words of greeting to the Association, and then came one of the happiest speeches of the evening, from Mr. J. W. Hughes, who gave "Our Guests" Mr. S. C. Stevenson, Secretary of the Council of Arts and Manufactures, also spoke, and entered into details concerning the work of the Council of Arts and Manufactures, in so far as the plumbing trade is concerned. Mr. McLaren and Lieut.-Col. Massey also spoke, as did ex-Ald. Clendinneng, wishing success to the Association Songs and recitations then became the order of the evening.

The Committee deserving credit for this most successful banquet was composed of Messrs. Joseph Lamarche, J. C. Jacotel, Joseph Thibault, W. A. Stephenson and Fred. Hortan.

THE PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The report of the examiners on the examination for admission as students and members of the above Association held in Quebec in January last, and recommending that Messrs. E. B. Staveley, D. O. Turgeon and Louis Bélanger be accepted as student associates, and Mr. Cagetan Dufort as member, was adopted at the last Council meeting of the Association, held on the 12th March.

The Committee appointed by the Association to revise the Montreal building by-laws, as requested by the Fire Committee of this city, have completed their task, and the new by-laws, as drawn up by the Association, are now in the hands of the civic authorities. The work has been found very onerous, the Committee having held semi-weekly meetings for the purpose for the last ten months. The by-law comprises one hundred and forty-one type-written pages of foolscap size.

At the request of the Ontario Association of Architects several members of this Association are preparing to send drawings for their approaching exhibition. All drawings will have to be delivered at the store of Messrs. W. Scott & Sons, 1739 Notre Dame street, not later than the 1st April at noon.

MONTREAL STREET RAILWAY BUILDING.

The Grand Jurors of the Court of Assize have brought in a verdict of "Not Guilty" in the case of Messrs. E. C. Hopkins, A. Gravel and Foreman McLaughlin, accused of criminal negligence in connection with the Street Railway building. Mr. G. T. Hammond, architect, of Cleveland, Ohio, has now charge of the building, the interior of which he intends to completely tear down, and have rebuilt ready for occupancy by the end of next autumn.

CUSTOMS DUTY ON ARCHITECTURAL PLANS.

IN order to insure uniformity in the collection of duty on architects' plans imported into Canada for use in the erection of buildings therein, the Controller of Customs has, under the provisions of sub-section 2 of section 65 of the Customs Act, determined the value of duty of such plans to be as follows :

Each set of original drawings or single set of blue prints of same, if brought into Canada as a substitute for the original drawings, 2 per cent. of the estimated cost of the building to be erected thereon.

Same, if accompanied by details, 3 per cent. of such estimated cost.

Details, or blue print of same, if imported separately, 1 per cent. of the estimated cost of such detail.

When additional sets of blue prints of the same set of drawings are imported, such additional sets of blue prints are to be valued for duty at $5 per set in addition to the value of the original drawings, or first set of blue prints imported in lieu thereof, as above.

AT the recent annual meeting of the Toronto Radiator Mfg. Co., the reports presented by the Secretary and Manager, Mr. John Taylor, were of a most satisfactory character. The Company have established agencies as follows : Canada—Montreal, Que. ; Quebec, Que. ; St. John, N.B. ; Hamilton, Ont. ; Winnipeg, Man. ; Victoria, B. C. ; Foreign—London, Eng. ; Edinburgh, Scotland ; Glasgow, Scotland ; Belfast, Ireland ; Antwerp, Belgium ; Hamburg and Berlin, Germany ; Auckland, N. Z. The directors and officers of the Company were re-elected as follows :—Joseph Wright, President ; David Carlisle, Vice-President ; F. W. Doty ; John M. Taylor, Secretary-Treasurer and General Manager.

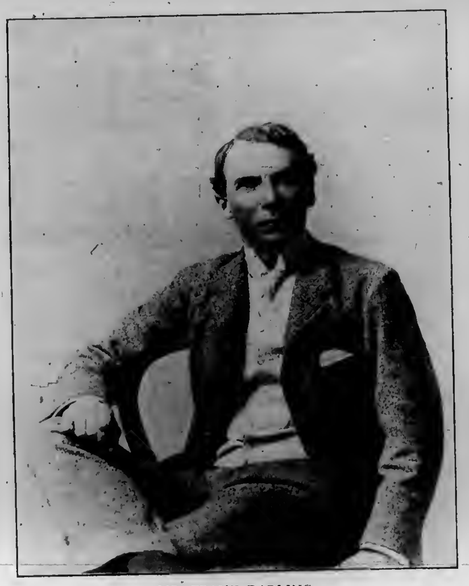
ILLUSTRATIONS.

PORTA DELL PALLIO.—SKETCH BY EUSTACE G. BIRD.

THIS gate built in 1520 A.D. is the west entrance to the city of Verona, in Northern Italy, and is an instance of San Micheli's wonderful ingenuity and taste in the mode of displaying pure and beautiful architecture with the requisites called for in fortifications. San Micheli devoted himself with great ardour to the practice of military architecture. The genius of this architect was of a very high order; his works are conspicuous for excellent construction as they are for convenience, unity, harmony, and simplicity, which threw into shade the minor abuses occasionally found in them—and our advice to the student would be to study his works with diligence.

"STOKESAY CASTLE"—THE GATEHOUSE.

Stokesay is an almost unique specimen of a mansion of the thirteenth century, fortified subsequently to the erection of the domestic portion of it. It combines in itself associations not only of the peaceful daily life of its inmates, but of that eventful time when this border land was the scene of forays and bloodshed, and happily preserved with very little alteration through the chances and changes which have levelled so many other similar structures of that early date. It presents many features of curious interest for the architect, the archæologist and historian, and the artist finds a gem of color and combination with a perfect setting.



MR. FRANK DARLING,
President of the Ontario Association of Architects.

The castle is situated on the left bank of the Onny, in the County of Shropshire, and within ten miles of the famous and better known stronghold of Ludlow. To the east rises a steep hill, on the summit of which can be traced the remains of a British camp—its sides clothed with firs; to the west a corresponding cliff, the lower slopes covered with hollies of great age and the ridge of rugged limestone. This was the site selected for the home of one of those lords of the Marches, who in the time of the first Edward held this border land under the stern feudal rule, and who had frequently to repel the attacks of the as yet unconquered Welsh.

The first objects which arrest attention on first seeing the Castle are the gatehouse and the moat; the latter surrounds the whole building and has a depth of about six feet and an average breadth of twenty-two feet. It is now used as a garden, and was once much deeper, being fed from a small stream coming down from the neighboring hills. The gatehouse, which has probably replaced the original drawbridge, is a fine example of a Tudor "black and white" building. Its timbers hoary with age, and stained by the rains of 300 years, have toned a silvery gray and are still in excellent preservation, and in many parts are richly carved, but in one or two instances have been cut away for new work of an order that is more useful than ornamental; and in cutting some of the main timbers, when the ugly chimney was erected to a more modern kitchen range, that side of the gatehouse has sunk, and the whole of the lower half was replastered upon the timbers which correspond with the other side. Over the ample archway which runs through the centre are displayed on the arch beam "The Rose" in a shield with lion paws as supporters, and flanked with rude carving foliated in low relief. On the opposite side, corresponding, are the figures of Adam and Eve, the serpent and the forbidden fruit. Two quaint figures surmount the pilasters—a man and a woman in dress of the fashion of the times—probably the founder and his wife, while at each corner of the house are massive oaken corbels, the carving being very bold and masterly, each of the four being of a different design, the one I have shown being the most perfect. The timber work of the upper story has been much cut away for windows, but the blank plaster panels have not been filled with timber strutts, but left purposely blank, either to be filled with ornamental plaster or as window spaces that were not required, and afterwards lath and plastered.

In the last century this gatehouse was often the resort of an outlaw, who successfully eluded capture by secreting himself in a small room entered by a trap door, but there is nothing of special interest in the interior, as it has been much modernized and is now occupied by a caretaker.

A door of great size, made ball-proof by two layers of oak plank laid over each other at right angles and clamped with large headed iron nails, and pierced for firearms, remains as a relic of the civil wars. The hinges and other iron work appear to be of earlier date, and were probably taken from other parts of the castle.

Crossing the court-yard we have the heart-shaped tower, unique in itself; on the left a banqueting hall with its chased beams and windows of early English tracery; the priests' rooms and deep well in the North tower, having an overhanging half timber story over the moat. The solar is a splendidly panelled room with a grand fire place, and there are some good carved square pews in the church close by that reminds one of an elaborate horse-box.

From the date of Domesday to 1241, with the exception of two intervals of forfeiture, the de Lacys held this and other manors. About 1115 the de Says were enfeoffed at Stoke by de Lacy—hence the name Stoke Say. Their ancestor, Picot de Sai, or Sez, a place in Normandy, fought at Hastings under William 1st. Five of the family are mentioned in connection with the manor. In 1240 the line of de Lacy died, when it passed through a daughter to John de Verdon, who died in 1274; then to Lawrence de Ludlow, again to the Verdons, Mainwarings and Cravens. Sir W. Croft was slain here in 1645. It now belongs to Dent Allcroft, Esq., who lives near.

After the civil war, Stokesay was ordered to be "slighted," or rendered incapable of defence, but in this instance only the battlements of the northern tower were removed and the rest left intact. It was at one time used as outbuildings to the neighboring farm house. Lord Craven carried out necessary repairs for its preservation, and Mr. Allcroft at considerable expense has just put it into an excellent state of repair, but has allowed nothing to be removed or destroyed, and thus is handed down to us a relic of the past, little known by architects, except in the immediate counties, so I trust this slight description will prove of interest to our brethren across the pond.—ED. SWALES.

RESIDENCE AT VANCOUVER, B. C., FOR CAPT. R. ARCHIBALD.
—R. MACKAY FRIPP, F.R.I.B.A., ARCHITECT.

Valuable stone quarries are reported to have been discovered at St. Raymond, Que.

THE LONDON COMPETITION.

WE desire to draw attention to the unfairness of the conditions under which competitive plans are invited for the re-building of Dundas street Methodist church, London, Ont. These conditions are as follows:

"The trustees do not bind themselves to accept any plan, but should they select one, and desire to use the same without employing the architect of such plan, he shall provide all necessary specifications and working drawings for the sum of $400—four hundred dollars.

"First drawings and estimates to be delivered to the Secretary in London on or before the 21st day of March, 1895, and completed specifications and working drawings to be ready for inspection and use of contractors on or before the 11th day of April, 1895.

"The architect to state in writing what percentage on his estimate he will charge to personally superintend the erection and completion of the work, and should the trustees engage him for such service, then the aforesaid $400 will not be paid for plans, it being agreed that the percentage named by the architect includes plans, specifications and superintendence of the work.

"Architects preparing plans will please withhold their names from said plans, and instead of name put thereon a distinctive mark, advising us under separate sealed cover what mark they will use.

"Kindly advise if you will submit plans.

Among the principal objections to these conditions, the following may be cited: (1) They do not guarantee that the best plans will be accepted; (2) Only one per cent. is offered for working plans and specifications, instead of 2½ per cent.; (3) Cheap work is invited by requesting architects to state *what they will charge* for doing the work where there is only one possible percentage which can be charged by respectable architects. We cannot see how any self-respecting architect can consent to enter a competition under such conditions as these.

TORONTO BUILDERS' EXCHANGE.

IN recognition of his valuable services as President of the Exchange, Mr. William Pears was recently presented with the following address: "In accordance with the unanimous vote of the Builders' Exchange, as expressed at the annual meeting held on January 21st, it is requested that you accept the accompanying cigar-case as a slight expression of the friendship and good feeling entertained towards you by your fellow-members. During your two terms of office as president of the Exchange, no effort was wanting on your part to promote the efficiency and usefulness of this association, and it is hoped that the accompanying memento may express in some degree the appreciation of your fellow-members. With best wishes for the welfare of yourself and family, we remain, yours truly, John B. Vick, Geo. Oakley, C. S. Boon, on behalf of the Exchange."

PERSONAL.

Mr. R. Mackay Fripp, F. R. I. B. A., of Vancouver, B. C., passed through Toronto last month en route for Europe.

Mr. Geo A. Clare, of the firm of Clare Bros., of Preston, Ont., has been honored with the Conservative nomination for the House of Commons, for the South Riding of Waterloo, Ont.

Mr. W. W. Summers, one of the oldest contractors in Hamilton, and well known in Masonic circles, died in that city last month. Mr. Summers was born in Hadleigh, Essex county, England, on January 2, 1822. He came to Hamilton in 1854 to superintend the erection of the Anglo-American Hotel, now the Wesleyan Ladies' College.

Intelligence comes from British Columbia of the death at the Jubilee Hospital in Victoria, of Mr. Frederick Toms, the well-known Ottawa contractor. Mr. Toms was attacked by bronchial pneumonia soon after his arrival on the coast, whither he went for the purpose of erecting the new Government building at Victoria. When the gravity of his condition became apparent he abandoned his contract, which was taken over by Messrs. Elford & Smith, of Victoria. Mr. Toms was a native of Newfoundland, and had been engaged on a number of very important works, making his headquarters at Ottawa, where his interment took place.

The news of the death of Mr. N. B. Dick, architect, which occurred at his home in Toronto, last week, came as a sad surprise to his many acquaintances. His death resulted from consumption induced by a severe cold contracted a year ago. Mr. Norman Bethune Dick was born in Toronto in April, 1860, and was the son of the late captain James Dick. He began his architectural education in the office of Messrs. Smith & Gemmell, of Toronto, and after leaving them went to Cleveland and spent considerable time there and in some neighboring cities. On his return to Canada he settled temporarily in Kingston, but subsequently went to St. John, New Brunswick, where the great fire afforded a splendid opening for one in his profession. He commenced practice in Toronto in 1879, and soon enjoyed a quiet but good and steady business, and in 1890 formed a partnership with Mr. A. Frank Wickson. Among the buildings erected by Mr. Dick were the Granite Rink, the Victoria Club House and Rink on Huron street, the Academy of Music, on King street. Mr. Dick was ardently interested in yachting, and has held the position of rear commodore in the Royal Canadian Yacht Club; he was one of the owners of the racing yacht "Zelma." He was one of the original members of the Toronto Architectural Guild, which preceded the formation of the Ontario Association of Architects.

The large Portland cement works erected by the C.P.R. at Vancouver, B.C., have been put in operation under the management of Mr. S. Warsup, late Assistant Superintendent of Messrs. Francis, Sons & Co., of London, Eng. These works have a capacity of 600 barrels per week. All necessary ingredients are obtained in the Province, limestone being procured from Texada Island and clay from Wharnock.

STAFF.

By W. J. HYNES.

THERE is probably none of the various departments necessary to the completion of our buildings so neglected and misunderstood as plastering. Amongst the many branches of the trade that require a better understanding on the part of architects, is staff.

Staff is a compound principally of plaster of Paris in which a large amount of strong fibre has been incorporated before setting, rendering the resulting cast very strong so that it will stand much rough usage; it may be sawed, nailed and handled much the same as wood. For many years English and European decorators have used similar compositions. Fibrous plaster, plaster and canvas, and like compounds have been used extensively in interiors. They have met with favor because artistic light in weight, easily secured and lasting.

Staff was first used as a temporary decorative material in the Paris Exhibition, where its use was confined to foliations and statuary. The success attending it there led to its adoption at the World's Fair, as the cheapest and best material for mouldings, reliefs, statuary columns—in fact the entire covering of all buildings, inside and outside, was staff, except the larger plain surfaces which were lathed and plastered.

To its use may be largely attributed the architectural and artistic success of the Fair. For the first time in their experience, architects found themselves free to design with practically no limitations. That this liberty was not abused, we have their work as evidence.

As at present composed, staff should not be used for any exterior work, unless for temporary purposes. Plaster of Paris, its principal component part, will not stand the action of frost, nor weather, unless protected by paint or other insoluble washes. At the World's Fair its use on exteriors was justified by the requirements, and the fact that it stood so well the winter of 1892-'93 is greatly in its favor, but there is nothing to justify its application outside on permanent structures.

These objections do not hold against its use on interior work. All that is necessary is a proper understanding of the material and its manner of application. To this end it must be understood that staff work is always cast in moulds. These moulds are made from different materials, as required by the character of the work to be reproduced. A free architectural design will require wood moulds for plain mouldings; plaster-piece-moulds for more intricate designs; white foliations and plastic designs are best reproduced by gelatine moulds which give a faithful copy of the modeller's work to the minutest detail, with all the necessary under-cuts and treatment.

When staff is being cast from the moulds the plaster composition is poured into them in a fluid state, and before this sets the fibre is incorporated. The cast, which results, is very strong, the fibre holding the various parts together even after fracture; it requires a saw to cut it, and nails can be driven into it freely. This admits of it being fixed by nails and screws to the joist, studs, brackets and grounds prepared by the carpenter, and the result is security such as cannot be obtained by the old lath and plaster work. As a covering for wood or iron work there is much to commend this material. Settlements and shrinkage cannot dislodge it when securely nailed. If not fire proof, it certainly is not inflammable, and is also a very poor conductor of heat. These qualities have led to many forms of plaster board, grooved plaster slabs, and other compounds similar to staff for lathing. Sections from three to four feet square are also made for ceiling covering, either plain or decorated, and can be panelled with mouldings or finished plain as may be desired. A staff cornice for an ordinary room does not compel the designer to confine himself to the outline of the angle; the thickness of material is not a consideration; it allows the greatest liberty. It is needless to enlarge upon the possibilities. The World's Columbian Exhibition furnished an object lesson that ought to be remembered.

Staff, like all other materials, has its place, and good sense will dictate its use; it is a covering and decorating material stronger and more lasting than plastering. In addition to this it is most suitable for decorating wood-work, running ornaments, capitals for columns, panels for pilasters, terminals for exposed construction trusses, brackets—in fact any decorations required.

One of the strongest recommendations this material has is its low cost. While the first cost of models in plaster are equal to carving in wood, staff reproductions are cheap; if enough are required from one design, a very low price can be secured.

The facility with which staff can be reproduced in almost any size or design, the faithfulness with which the artist modeller's treatment can be duplicated, are factors that will in time work a great change in the architectural treatment of interiors. Relief work and mouldings will replace the flat surfaces which are now so common. The architect will have an opportunity of stamping his individuality upon interiors, instead of this work being left as now to the modern decorator and his wall paper. A building may have a permanent character all its own, interiorly as well as exteriorly, and not to be subject to whimsical changes of style. This will call for careful study of interior architecture and cannot fail to have a good effect.

PAPER ON "ENGLISH METHODS."*

By Frank Baker, A. R. I. B. A.

The subject of my paper "English Methods," is obviously one which it would be impossible to go deeply into, in a small paper but a short resumè of some of the most striking "methods" may not prove interesting.

The absence of extremes in the climate of England, of the brilliant sunlight, and severe heat or cold, and the continual dull or semi-dull atmosphere, impresses us at once with the impossibility of getting a sparkling or brilliant effect in exteriors, no matter what materials are used, and the architects many centuries ago as now, have wisely decided that there is no use attempting to get an effect such as is seen in America, or France or Italy, in the English climate.

Some venturesome architects of later years, have attempted to relieve the admitted monotonous appearance of the cities and towns, by erecting buildings of terra-cotta and brick, both combined in bright colors, and by working in lighter styles, as Spanish Renaissance, Florentine, Flemish, etc.; the former, however, soon lose their lustre, and the weathering of the latter, presently made apparent their unsuitability to the climate, so that the man who abides by tradition, achieves the greatest success in the long run.

An illustration of this was given in the recent competition for the completion of the South Kensington Museum, at London, when amongst the eight designs submitted by selected architects (four selected by the Government and four by the R. I. B. A.), one was sent under the motto "English Tradition," illustrating a building of excellent plan, but with a cut stone exterior, of the heaviest possible character, much more suitable for a jail or bank than for a museum of the nature of the S. K. M., and the ludicrous effect of this building in juxtaposition with the present building, on Exhibition road, (designed in light Italian Renaissance style, and constructed of brick and terra cotta) the Natural History Museum and the Imperial Institute, can easily be imagined. It was not accepted.

Surrounding existing conditions were entirely ignored by this competitor, who apparently had well in mind the effect of climatic influence, yet had the expert in the cases of the above mentioned buildings selected designs in keeping with the climate, the design of "English Tradition" would undoubtedly have been a close competitor, as with one exception the other designs were to my mind quite unsuited to the English climate. Thus it is that the successful buildings are those of strong substantial design, emblematical of the climate, and we all know how eminently successful many of them are.

The foregoing has led up to the importance of considerably surrounding conditions in designing, a question of course of first importance, and yet frequently ignored; many instances of the success of adopting it, and of the failure by neglect of it, could be sighted, but one occurs to me which will illustrate the latter. An architect having under way a city building of importance in London, observed when his building was showing well above the hoarding, that preparations for rebuilding were being commenced in the adjoining premises. He very courteously on discovering the identity of the architect, wrote to him offering to send him a set of plans of his building, so that the neighboring architect might govern himself, in finally deciding upon his exterior, materials, skyline, etc., etc. This gentleman unwisely returned a reply that he had already determined upon his design, and he did not contemplate altering it. The result, as might be expected, was an anomaly; the last built building being of less importance, like its architect, was completely overpowered, where a little care and judgment, might have made an harmonious whole. English method in the use of materials, both with regard to appearance and construction, requires little comment; its excellence in each direction, and more especially the latter, is or should be well known.

Color as applied to interiors, is like all exteriors, usually very quiet, probably another effect of the climate; of brilliance and sparkle, there is none; the grandeur of the weather stone, or the rich glow of the oak, black with age, is more to be noticed than lavash coloring or gilt, so much seen in the neighboring Republic, France. Go from the parish church to the Cathedral, from the Mansion House to the College Halls of Oxford, from even the most brilliant theatre, to St. George's Hall, Liverpool, and color will be found used only in a quiet way.

Of planning I have nothing to say, except that in almost every case, as it should be, the elevation is made of minor importance to the plan. Of "English Methods" in construction, there are many to comment upon, and some perhaps to criticize. Foundations are nearly always of cement concrete, and in most if not all cases, the concrete is continued about 8" thick under the whole building; whether basements are excavated or not, the ground beneath the floors is covered. Damp proof courses of asphalt or slate, are built into the foundation walls, below the point on which any wood-work rests. Dry areas with heavy retaining walls are constructed around all buildings so that no foundation walls come against the earth, and these are carefully drained. Perhaps one of the most noticeable instance of the use of concrete as a foundation, is under the Victoria Tower of the Imperial Institute, where the masonry starts from a block of concrete 40 ft. square and 18 ft. thick. Coke breeze concrete is largely used for the construction of fire proof floors, staircases, etc., and from its lightness is much to be commended, and might be used in this country with good results.

The grandeur of English stone work is typical of the country. Here is no sham, no paving slabs on edge, every stone laid carefully on its natural bed, and where backing of brick is used, it is generally indicated on the face, as in one large public building constructed of Portland stone, where the architect has caused two courses of brick to be carried around under the main cornice, and on noticing this the observer is not surprised to see that the interior courts are walled with brick, and realizes at once the nature of the building. Stone hanging staircases, worthy but difficult of imitation, are frequently to be seen, cornices and ornament which would naturally be stone, are stone, not copper or iron painted in imitation. Finally, enough cannot be said of the beauty and durability of stone groined roofs of which so many are seen. In such things is the secret of England's supremacy, and when will our capitalists learn the advantage to the country, to themselves and their posterity to be gained by investing sufficient money to guarantee the substantial and lasting character of their buildings.

Wood, as applied to heavy construction and joinery, is used regardless of expense; when applied to roof trusses, etc., the timbers are always of far larger scantling than calculation shows to be necessary, but the Englishman says 'we will be on the safe side," and doubles it, and none but good results can arise from this, though there may be an apparent waste of material. The idea of our slow burning or mill construction is, I suppose, taken from the construction of the floors in the average country residence in England, as they are constructed on the same principle.

Of steel or iron construction as applied to architecture, this is to be said, that if the building is of any importance an engineer is called in to assist the architect, and if the building is of minor importance, it were better that the engineer had been called in, or the metal left out, for English architects do not profess to be engineers, and what we consider of first importance here is entirely of secondary moment there.

In sanitary science the Englishman now, as always, sets us an example from which much can be learned. The system of carrying all soil pipes on the outside of outside walls is a good one, and though it is said that our severe climate prevents our adopting this principle here, it is likely that we will come to it in some form eventually. Perhaps a well ventilated brick flue might be constructed to contain these pipes, but something ought to be done to get them outside of the building.

The disconnecting chamber is another excellent device used by English architects. A chamber about 3 ft. cube is placed in the ground in close proximity to the building, and into this the main drain and all connections are brought. The main pipe is halved from where it enters the chamber to where it leaves it, and the cement bottom is sloped up to the sides from the top of the lower half which forms a trough. At the outlet of this pipe has a double trap with a cleaning eye, and at all angles a cleaning eye is placed. The disconnecting chamber has an air-tight cover, and is constructed of solid masonry. Ventilation pipes are taken from it, clear above the buildings. Sink wastes, and main water pipes are made to discharge in the open; the pipe is severed, and discharges on a grating, covering a trap leading to the pipe which connects it with the disconnecting chamber; the latter in the case of a sink is always a grease trap.

Lavatories are, when the money to be expended allows, luxuriously fitted up, second to none which I have seen in any country, and in this respect, the lavatories for the public use placed beneath the pavements in many of the principal squares in London are not far behind. New York and Paris have much to learn in this way.

The heating of public and private buildings has of late years been receiving more attention from English architects. The old open fireplace is found inadequate, or the hardy Saxons are losing their strength, but perfection or even semi-perfection which we Americans have achieved in this respect, has not yet been reached by the Britisher at home.

Great perfection is reached in the ventilation of large theatres and rooms of assembly, however; in the modern theatre the top gallery has just as pleasant an atmosphere as the pit.

In the preparing of drawings the thorough methods of the English are again evident. More care in drawing and correctness of scale, with a smaller number of figures and notes is a feature. Some architects prepare working drawings at one sixth scale, the object being to prevent mechanics roughly scaling off with a foot rule and forcing them to use a proper scale, which gives them the exact dimension. Full size details are all carefully drawn and inked in on good paper and on small sheets if possible, none of the unwieldly rolls of full size details, so common here, are ever seen in England. Half inch or inch scale details, of all facades are always provided. Perspective drawings are beautifully finished and care is taken to have surrounding conditions accurately drawn. Each working drawing bears the reference number of the job, the drawing number and date of making, and a book is kept in the office with a memorandum of when and by whom each drawing is taken away. Sun prints are used a little, but not universally. Specifications are written and quantities estimated by a "Quantity Surveyor" for whose payment provision is made by the contractor.

Of professional practice in England, it is at once apparent that the profession is on a sound and excellent footing. The R. I. B. A. has done much good work, and its examinations offer a test of knowledge which is eagerly sought. The exertions of the late Mr. Street, combined with those of the Royal Institute, have done much to adjust the former trouble with competitions. Some fifteen hundred architects signed a memorial, promising to abstain from entering any competition, unless a professional adjudicator was appointed. The result of this was at once seen and the young practitioner has since had a better chance of becoming established in practice. Surely with our Association, it would be easy for us to arrive at this result, and I trust before long to see something of the sort done, and every architect must see that the final result will be for his own good and the good of the profession. Another evil which threatens to upset the profession in Canada, if not remedied, though not so apparent in England, is that of cutting rates of commission. Members of the R. I. B. A. sign a declaration

*Paper read at the fifth annual convention of the Ontario Association of Architects.

not to cut rates, and Toronto has a Guild which, it is reported, requires a similar qualification for membership. This, however, governs only a few, and a movement which will cover the whole field is sadly needed. What is an architect to do, when one would be or erstwhile client, after another says, "Well, I should like to have you do my work, but Mr. —— offers to do it for one and one half per cent., and unless you can meet that I will employ him?" In England capitalists realize that it is false economy to employ a cheap rate architect, and fortunately many of our capitalists do the same, but the evil is a full fledged one and will be difficult to correct.

In addition to the Royal Institute, London has an Architectural Association, and those students who are members of this have an opportunity of visiting works of importance, in company with competent lecturers, and many other advantages in preparing themselves for practice.

In conclusion, I cannot do better than to recommend every architectural student to include in his career a course of study in England of English methods; very few of them have been mentioned in this meagre paper.

POINTS ON ACOUSTICS.*

By David Gunn Baxter.

Acoustics, the science of sound and hearing, it is to be regretted, is but dimly understood. We are groping around in the dark, following a will-o'-the-wisp that we seem seldom able to catch, and when we do catch it, it appears more by chance than by a previous certainty of scientific fact.

Instead of using acoustical science as the primary basis in constructing the design of a public speaking place, we too often leave it to a mere secondary place, letting it take care of itself, and apologizing for bad acoustics by an artistically proportioned or decorated interior.

In this paper I shall not delve into theory, but rather glean over some of the principal points in practice. In designing a church, theatre or public hall, the first consideration should be proportion, length and breadth, with galleries, to seat our required audience, and proportionate height of ceiling to accommodate all. Saunders' experiments give as a result that an ordinary speaker, in the open air on a still day, may be heard distinctly 92 feet in front, 75 on each side and 31 behind. Wren, however, claims less—his observations giving 50 feet in front, 30 on each side and 20 behind. It will thus be seen that the circumscribed area will seat, roughly, about 1000 people. This area being enclosed, and galleries inserted, as many as 2000 persons might be accommodated; and allowing for conduction and retention of the sound waves, we might increase the area to accommodate 4000 or more.

Large buildings may roughly be divided into two classes—1st, those in which the audience hears by direct radiation only, such as theatres or music halls, when high shallow rooms are advisible; 2nd, those in which the audience hears by conducted radiation, such as cathedrals or other large churches without galleries, when long low buildings are best. In either construction it is bad policy to have the auditorium contain any more air than is absolutely necessary. The more air there be, the more vocal exertion necessary to set it in vibration, and for ventilation have good quick circulation, preferably from the speaker to the rear, or what is still better, use the "plenum" system, which is exceptionally good, on account of the heavier sound wave produced in the slightly condensed air.

In designing an auditorium to seat a given number of persons, a certain floor area is required, but how to divide this required area into main floor and galleries, to come within a proper proportioned width and length, and what shall be the contour and height of ceiling, are indeed vexed questions, calling for a great deal of personal observation and ingenuity; bounded by no iron rules, governed by few fixed laws, affected by the restrictions of site and finances, these limitations, together with the whims and caprices of the proprietors, makes the problem to the architect indeed a difficult one.

For lecture and school rooms a height of 2, depth of 3 and breadth of 4, has proven extremely satisfactory, the speaker being on the longest axis. For small churches, court or other rooms, where the speaker is on the shortest axis, a height of 1, width of 2 and depth of 3, has proven good.

On account of the nodal points established by the columns in nave and aisle churches, a length of 4 to 5, width of 2, and height of 1 to 1¼, works well; this is for cubical contents, but on account of the lower ceiling in the aisles, the nave ceiling may be greatly increased in height over the above proportions. On account of limitations of site, no definite rules can be given for theatres; generally speaking a height of 3, breadth of 4 and length of 5, is satisfactory. Many successful Chicago theatres are of this proportion.

In all buildings for public speaking, except perhaps cathedral churches, floors should be constructed on the isaconstic curve plan, straight slopes being as bad for sighting as a level floor, and if anything, worse for the passage of the sound curves.

Ceilings greatly affect sound; where flat, they should never join the walls at right angles, but in sweeping curves or coves, and are best lightly panelled; skylights, if introduced, should have a sash at the ceiling line to cut off the contained air, which, starting in a sympathetic vibration of its own, would cause an echo, or if not, would form an eddy, much to the detriment of the free passage of the sound. If possible, it is well to bring down the ceiling on a regular curve or jogging slope, as low as possible above and behind the speaker. This considerably reduces the volume of air to be set in motion, eliminates all chance of echo caused by the eddying of sound vibrations at this point, and directs the waves out into the hall. In theatres, a line should be drawn from the top of the procenium arch to the top of head room over the highest gallery at the rear wall, and the ceiling kept on this line—of course not a straight slope; cut the ceiling up into steppings, coves and panels. This helps artistically, and also breaks up the continuous reverberation which would cause echo from the rear wall. It is also advisable to have theatre ceilings follow the curve of the proscenium arch for some little distance out, at least as far as the last box. Vaulted ceiling churches are exceptionally good for speaking in. The ceiling breaks up continuous vibration and the columns help to direct the sound forward, by forming nodal points on which the sound curves turn.

Walls have no mean part to play in the acoustical properties of rooms. They should always be broken with slightly projecting pilasters or shallow recesses. In theatres it is advisable to draw in the walls at the boxes, at an angle of say 45 degrees or even longer; this contraction at the proscenium, together with the sloping ceiling, gives the interior a speaking trumpet or funnel shape, which is extremely easy to speak in. Like the expansion of the circles produced on still water by the dropping of a pebble, so also do sound waves expand as they recede from the speaker. In addition to this, all air space is cut off where it is not required and where lines of sight die out; the less air to be set in motion the easier it must be on the speaker.

Galleries are never good when of excessive projection; the greater the projection the higher they should be. The ceiling underneath and the floor below should on section be shaped like a wedge, not generally as is the case, small end out and big end in, but with wide end out and narrow end in, thus counteracting the absorption of sound by the soft clothing of the audience, and the gradual lessening of power in the sound as it recedes from its source. Besides, this shape is a great gain in structural strength, the only objection being, of course, ventilation, which is extremely hard to perfect in this construction, especially if the gallery be low.

The proper location for the choir in non-ritualistic churches is hard to arrive at, and varies with whims of the proprietors altogether too much. In front and below the preacher is not admissable for several reasons. They should not be behind him and on nearly the same level, for a great deal of effect is lost from the discourse by the preacher being surrounded by a halo of beaming femininity; therefore I incline to believe that a choir is better when raised up above the speaker's head and placed in a groined recess. This form raises up the volume of choir sound above the heads of the congregation, and there being a recess, the tendency would be for the sound to travel in a greater volume and farther ahead

In designing ritualistic churches, care should be taken that the chancel arch does not project more than a few inches on each side of the walls on the chancel side. If the chancel width be contracted very much at this point, the sound therefrom will be greatly muffled and appear flat and dead.

The orchestra in theatres should receive careful consideration. Around it resonant materials should be used, and the shape must be such that the sound will be directed up and out over the audience.

All buildings present obstacles and auxiliaries to the passage of sound and the direction of it properly over the audience. In designing, auxiliaries can often be introduced, but as they are of doubtful result—doubt, not only as to their proper working, but that they will not prove formidable obstructions—it is advisable to discard all experiments thereon and confine our attention to the elimination of as may obstacles as possible.

A great deal might be said about what materials are best to use on the surface of our work, and what are not. Thin pine boards in long lengths are exceedingly good; or in plaster work, I know of nothing better than 'Adamant,' on account of its extreme hardness and uniform elasticity. Any soft covering is never good, as it deadens sound by absorption. Walls and ceilings vibrate in unison with the vocal chords of the speaker, and any lining which is resonant and elastic enough to keep up a sympathetic vibration throughout the entire wall or ceiling length is only admissible for use, preference being given to such materials as are capable of sustaining or augmenting the vibrations. Again, in rooms where an echo is perceptible, while the room contains its full capacity of auditors, a judicious use of drapery or curtains will generally remove it. If these be not admissible, then some soft surface covering, over that part or surface which causes the trouble, will have the desired effect.

—In rooms where the acoustical properties are poor, to improve them resonant materials for walls and ceilings are usually good in result; often only a sounding board behind and above the speaker will have the desired effect, or it may be necessary to change the shape and contour of the walls and ceiling.

*Paper read before the Ontario Association of Architects.

PUBLICATIONS.

General Lord Wolseley makes a most important contribution to the literature of the China-Japan war in an article for the February Cosmopolitan.

Toronto Saturday Night has grown to be more than a society paper, as that term is generally understood. As a literary, artistic and social weekly, it occupies with credit an unique position amongst Canadian publications.

The 1895 Catalogue of the Toronto Steel Clad Bath Co. contains descriptions and illustrations of the various styles and sizes of baths manufactured by the Company, and numerous testimonials. The artistic appearance of the catalogue is worthy of mention.

There has reached our table in pamphlet form a copy of a paper on "Hudson Bay—Proposed Utilization of its Land and Water Resources," by Chas. Baillarge, architect and C. E., President of the Province of Quebec Association of Architects, read before the Literary and Historical Society of Quebec on the 7th inst. The paper sketches briefly the size, climate and resources of Hudson's Bay, and prognosticates that before the end of the century railway communication will have been established between Quebec and this northern territory by the extension of the Lake St. John and Temiscamingue roads. A colonization scheme for Hudson Bay is also outlined. The paper will well repay perusal.

A CHAPTER FROM MY NOTE BOOK.—BUILDING METHODS IN ROME. *

By M. B. Aylsworth.

This audience being composed of architects, the object of these cursory notes shall not be to treat of architectural styles, their origin, development or peculiarities, that subject having become threadbare. Familiarity may not necessarily have bred contempt in the minds of all, or any, but too much devotion to such study may have wrought some evil, which might here be hinted at.

Ancient architects designed the grandest and most beautiful of buildings, fitted in all parts for their intended purpose, using the best materials to be obtained and suited to the climate and other local conditions, without thinking of, or publishing the name or style of order. Classification has been the work of later students, many of whom have noted the peculiar or pleasing forms, while missing altogether the spirit of the designer.

Through superficial study of such classification the laity have become familiar with the names thus applied, and this little knowledge has endangered and retarded the development of true architecture from the Renaissance until now. The modern architect, expecting to be asked to name the style of his design, and not having the boldness to say he disregarded ancient styles, must adopt one of them, and probably disfigure the building by the incongruous or needless use of certain features, or their imitation in perishable material.

Without this supposed necessity, out of our modern requirements, resources and limitations might be evolved suitable, durable and pleasing buildings of a style that in succeeding ages might also be dignified by an appropriate name. As it is, how may this age expect to be known or described, when in turn it shall be referred to as ancient? Will there be any remains of it whatever 2,000 years hence?

Building methods, though always affecting the development of true style, have not always been so fully described as the finished form, and some of these methods, observed during a visit to the "Eternal City," will now be referred to.

During the early ages, known as the time of the kings, the building materials seem to have been wood and the volcanic rock of the neighborhood, called Tufa. Of the former nothing has survived, though Egyptian wood much older is plentiful. Of stone structures without mortar, there are portions of the walls of Romulus, the Mamertime prison, cloaca maxima, and other remains.

In later periods, probably through expeditions from the east, the properties of clay and cements became known. There are now, and have been for ages, extensive brick yards in the suburbs of the city, mostly the property of His Holiness the Pope. There is also in the vicinity a reddish clay called Pozzolani, which, mixed with common lime mortar, makes it hydraulic and very strong. The great strength of this mortar, after use in brickwork, further led to the use of concrete, out of which grew the peculiar Roman methods of walling and vaulting still in use. This was their own, and only invention, but was one of very great importance.

The Romans became a conquering nation, and amongst the spoils of war great numbers of beautiful columns and sculptures in the rich marbles, porphyry, alabaster, &c., were brought to Rome, with architects, sculptors and artizans as slaves to set them up. Through the use of these, applied to their rude buildings, arose the Roman style of applying architectural forms having no relation whatever to the construction of the building. From the interior use of these columns came the basilica, and finally the cathedral. The earliest dome covers the lower dungeon of the Mamertime prison. This is not a true arched vault, but is formed by the rapidly oversailing stone courses of the sides, until they meet to form the floor above. In this dungeon St. Peter caused water to spring out of the solid rock, so he might baptize his jailor. The spring is still flowing, whether St. Peter was ever in Rome or not. The cloaca maxima is probably of later construction, and is a circular tunnel of true arched stonework. All later vaulting is either of brick rims on edge and keyed, or brick simply bedded flat in cement, or they are formed entirely of concrete, in which gravel, broken stone or brick and even lumps of clay are used. Over church naves and similar structures, the form is semi-circular, but over ordinary rooms is elliptical, often very flat and thin, wasting no height. The haunches are always levelled up at the same time, and when all has set with the walls, it is like a solid stone. That grandest of domes the Pantheon, is merely the largest example of what was, and still is, in one form or other, the common ceiling of all ordinary rooms. It is a solid mass of concrete, tapering from a great thickness at the springing, to a comparatively thin shell at the top, and contrary to the general rule as domes are built, is flatter outside than inside. The walls of the building therefore, 20 ft. thick and also of concrete, have to sustain no outward thrust, though the span is 143 feet. These walls appear as if of well laid brickwork, an unusual sight in Rome, but this is merely for the most part a facing of brick, laid or built up along with and to retain the concrete until set. To form the better bond with the concrete, the inner brick are wedge shaped. This brick face was again covered with stucco and marble veneer, and finished with marble pilasters, cornices, balustrade and statuary, now all removed, though the massive stone portico remains, with its granite columns 40 feet high. The outside of the dome was covered with gilded tile, carried away some 1200 years ago and sometime since replaced by lead. The inside with its deeply coffered soffit, was enriched with heavy bronze plating, removed and recast, first into cannon and afterwards into the canopy, 90 feet high, over the high altar in St. Peters'. This great building has but one entrance and no windows yet is flooded with light from the circular opening in the centre of the top, 30 feet in diameter, though appearing from below not one third of that. Storm and sunshine falling through for 19 centuries, have wrought no more damage than would a single year in our climate and buildings.

Rome has no doubt passed through many building booms, and is still disfigured by many evidences of the last one, some years ago. Dozens, if not hundreds of large buildings, 4 to 7 stories high were erected, many of them still unfinished, though not perishing as they would here. These contain a great many rooms, usually surrounding a square central court, and in the case of chapels, have arcaded galleries from which the several lower stories are entered. The court is not roofed over, but is nicely paved and opposite the main entrance has always a fountain, cascade or grotto, with more or less sculpture and foliage about it, and the water flowing perpetually. The ground floor rooms opening to the street, which may be very wide or as narrow as 4 feet are rented for stores, workshops, tenements, stables, &c., the upper portions as hotels, flats, &c., and even in palaces, the second story is generally rented as tenements; the palace proper, with its higher ceilings and magnificent rooms, beginning with the third story.

In Italy no building operations have ever been carried on except by the state, the church or the nobility—the great unwashed being retainers or tenants, paying rent or not. The present nation is composed of a great many former principalities, duchies, &c., each with its royal family, and when united, some 25 years ago, from one of these was selected an hereditary king. In all these cases the title descends to all members of the family at their birth. Hence the frequent mention of princes and palaces. The only other buildings are monasteries, tombs and theatres—churches and chapels being nearly always an adjunct to the palace or monastery.

These buildings, which might be residence, museum, store or factory, are fireproof, and should be inexpensive, being constructed entirely of the commonest brickwork, with all ceilings flat vaulted in brick or concrete, the haunches levelled up to form floors of cement, tile, marble or mosaic. The mosaic floors in many museums and palaces of to day have been removed from the more ancient homes of the Caesars, and with their rich and everlasting colors blending like brushwork, no more beautiful or durable flooring can be imagined.

Balconies, theatre galleries, &c., are formed by very flat and thin arches of rudest brickwork, or of concrete, springing from light iron beams, projecting or supported. Pilasters, pedestals, brackets, cornices, &c., are also roughly formed in brickwork, the whole afterwards to be completed in stucco, adding also to their strength. After the raw brickwork has stood for a year or more to settle and season, may be for centuries, the frames are set in openings and the finishing commenced. These frames may be of pine or of marble, and may have marble or stucco architrave finish, oftener plastered jambs without casing, and never is any wood used for casings or base, floors, partitions or stairs. The effect of lines of moldings for casings, base and room cornices, in common buildings will be produced later by shading in distemper, as part of the decoration.

Though the roughest of pine is used for doors, sash and blinds, their joiner work is excellent. Inside and outside shutters are used, and casement sash in all cases. All are heavy, fit perfectly, and the hardware is of the best and most durable description. Doors of very great age may be seen, of cedar and walnut still in the raw state, with panels, 2 feet wide and without sign of shrinkage. They are not exposed to furnace heat, they are in a dry climate and uniform temperature. Large doors or gates entering the court are made in pairs, very heavy, and are thickly studded with large pyramidal headed wrought iron nails. Such doors always stand open during the day. Just at this door or passage is the office of the porter, a person always in demand, and indispensable to the stranger. In all royal palaces he is a most imposing and gorgeous flunkey, selected for his great stature, good looks and stock of ready information. He is robed in scarlet with gold lace and cocked hat, yet accepts a tip of half a lire or ten cents more thankfully than a dollar would be taken here.

Church doors are nearly always open, but are provided with a heavy padded leather hanging, to shut out street sounds and avoid the constant banging. A lower corner of this will be lifted aside by one of the beggars always at hand, who will very gratefully accept the smallest copper coin. Visitors walk about freely inspecting every part of the interior, while mass may be going on at any number of the altars, or they may be conducted by an entertaining sacristan, priest or monk to the more sacred or interesting places and objects; tip from 10 cents to a dollar.

The exterior of buildings, generally will receive a finish of stucco, grey or colored, or of marble or a combination of both, forming pilasters, brackets, balconies, cornices, &c., to represent cut stone. In Rome the object is not to deceive, but if it were it would be most thoroughly accomplished. In that climate everything is durable. The traveller going from Paris to Rome would suppose the latter to be built of stone, while going from Rome to Paris he would suspect the use of stucco, and would be mistaken in both instances. The new "Banco Romano," however, directly in front of my hotel, was being built of stone as if in Paris. The building was quite sound, even if the institution was rotten! Indeed this street, "Via Nationale," has been engineered on Napoleon's idea. It is a new street in an air line from the modern railway station just inside the walls, direct to the ancient heart of the city, cutting down hills, levelling up valleys; hiding ancient ruins and slicing off palaces, gardens, &c., doing much more damage, in the opinion of the antiquary, than can be made up for by the magnificence of this modern innovation.

Roofs are in many cases left flat, and finished in cement, the same as floors, often supporting a considerable depth of soil, with orange and other trees, gardens, pavilions, statuary, &c. Lead is used on domes and similar structures, but the almost universal roof covering, from the palace or basilica down to the farm outbuilding on 4 poles, is the common pan tile, laid to about a quarter pitch. Such roofs have wood and iron framing, and this is about the only timber used in buildings. In such cities fires are of very rare occurrence. Only in a basilica could great damage be done, while in ordinary buildings the roof might burn off without in the least disturbing the inmates below.

Coffered ceilings are to be found only in basilicas or other very large halls extending up to the roof, as when a court may be roofed over. In such cases very heavy masses of enriched wood or stucco moldings are used, colored and gilded, and the panels filled with fresco paintings. To see and study these comfortably mirrors are used. All interiors are more or less enriched with modelled stucco, gilding, glazed porcelain, mosaic, precious marbles and real or imitation fresco. America affords no opportunity of enjoying the glorious effects of fresco. Our buildings have many windows but scanty light. Roman buildings, such as churches, art galleries, &c., have no windows as prominent features, yet are flooded with light, and this is partly due to the reflecting properties of fresco. Where dust and smoke, flies and cobwebs are such disfiguring agents as with us, it is difficult to understand how those wonderful inspirations of the grand old masters can have been preserved so many centuries beautiful and perfect, while the great quantities of such work is incredible.

In our business and similar buildings large spaces are covered and built over by the use of iron columns and beams, whereas, the Roman builders use large square brick piers and elliptic arches, from which spring the vaulting. The brickwork is always covered. A very few recent examples of excellent pressed brickwork may be seen, but its foreign extraction and aspect are painfully apparent. Stores usually consist of one or more cavern like rooms, with arched opening toward the street, the plate glass of doors, etc., held by the slenderest lines of wood or metal, more like show case construction. Rome has, however, one large departmental store block, with light all around, of modern design, but of Roman construction. Stairs, when not marble or other stone, are built of brick and finished in stucco to look like marble or alabastar, with balustrade in same finish or of iron.

Rome having a church for each day in the year, and a few to spare, and all of the same faith, not much church building is now in progress, though perhaps not one of these can be said to be completed. Work may be going on continuously, as for instance the mosaic in St. Peters, or may be resumed at intervals of possibly a few centuries. They are mostly built in the manner described, of raw brick work, with barrel vaulted nave and transepts, with central dome, cross vaulted aisles and the whole buttressed by dome covered chapels. The interior, and especially the chapels, may have received the most extravagant finish and decoration, in numerous instances costing millions of dollars, while the exterior remains raw brickwork, apparently a ruin, though many have at some period had stucco or stone fronts added as a veneer, by Michael Angelo or others of the old masters.

St. Peter's dome consists of an inner and outer shell of brick and concrete, the ascent being between them by steps of brick formed on the inner shell, even the lantern being similar. The ball on top and supporting the cross, is of copper over an iron frame, and into it may ascend comfortably 12 men at the same time. The ascent to the main roof is by a brick paved spiral incline, so easy and roomy that in a similar ascent in the tower of St. Marks, Venice, Bonaparte and two of his officers rode their horses to the top. It has been stated in print that on the roof of St. Peter's is a village of several hundred workmen, with their families and even domestic animals, gardens, &c. This is not true, though there might be plenty of room. In the vatican palace adjoining there is ample room for the 600 Swiss guards still maintained by the Pontiff, besides other hundreds of his subjects still remaining faithful. In St. Peter's the great number of large altar pictures, once frescoes, have been carefully removed and pieced together again in frames, to enrich other churches and museums, while their places have been as gradually filled in with the same pictures reproduced in everlasting mosaic, of which the greatest production is carried on within the vatican. The great dome and its lantern are now also entirely lined with mosaic. The tombs of many of the popes in St. Peters are magnificent groups of sculpture, but Pius IX at his death directed that his body be laid in a lower chapel of St. Lorenzo, outside the walls of Rome and leading down into the catacombs. He desired no monument, but to be interred in the simplest manner, just facing the tomb of St. Stephen. His wishes were carried out, but are now being disobeyed in this manner. The whole interior of the large apartment is being lined with mosaic, in which is interwoven the coats of arms of all the Bishops in the world, a most elaborate work and costing over a million dollars. In speaking of the richness of these churches it is to be remembered that the interiors are referred to, and particularly their chapels and altars, where are to be found many of the masterpieces and richest gems, gathered into Rome during all ages and from all quarters of the globe.

The largest churches are generally basilica in form, with a great variety of columns, &c., from ancient temples. The most beautiful is St. Paul's, outside the walls. Its flooring and rows of immense columns are of highly polished marbles. The ceiling of the nave is in coffered, decorated and gilded panelling, while the triforium bears large medallions of the whole long list of Popes down to date. Here are also the most beautiful cloisters of the Roman church. Though stained glass is not usually a prominent feature there, this church sustained the loss of half a million dollars worth of it, caused by the explosion of a powder mill in the vicinity a few years ago. In St. Peter's are placed twelve beautiful columns from Solomon's temple, and from their form are modelled what are called easter candlesticks. The past and present, pagan and Christian, are so visibly blended everywhere there, that nothing need be doubted. Why spoil the charm? The citizens of Trastevere, a certain quarter of Rome, claim to be the pure and undefiled descendants of one of the prehistoric tribes. On certain opposite street corners are situated exact pairs of churches. Several churches are closed except on the festival of the patron saint. In the city are no less than 80 churches dedicated to Santa Marie.

There are now at least a dozen Protestant church communities, only one having a building deserving notice, the English church, a design by Mr. Street. These are but little known to the Romans, and probably few would know whether the term referred to Christian or pagan! though there is a Protestant cemetery also.

One ancient tomb, known to be 1900 years old, is a perfectly preserved pyramid of white marble, externally, at least, 116 feet high. The greatest of the Egyptian obelisks are set up in the various squares, the largest 104 feet high, or with its pedestal 153 feet, and first erected 34 centuries ago.

There is usually little or no provision for warming buildings, except that supplied by fire places, and as foreigners demand fires, stoves of the most useless character are set up in their rooms, and frequently may be seen small smoke pipes carried through the outer walls in rows at each story. The better houses of course have stationary cooking ranges and more or less plumbing. Instead of the American self-feeder may be seen specimens of what are known as Dutch stoves, very high and built of decorated, glazed porcelain. A fire started in one to-day might begin to warm through before next week. For warming the hands and for cooking purposes, the portable brasier is common. Hundreds of tenements have never had a fire in them for any purpose. A brasier of coals on a tripod, in the street serves to do the cooking for a neighborhood.

The fuel is generally charcoal, or mulberry twigs, cut off with the silk cocoons, dried, and sold in bundles like sheaves of grain. An amusing sight on a country road, is a load of these bundles, looking like a load of hay, moving along with no visible team or waggon, but on close inspection may be seen the slender legs of a donkey on whose back the load is bound.

Hot baths are not so frequently required in so clean a climate, and are an expensive luxury, demanded only by the foreigner. Hot tea or coffee is hardly known amongst people where wine is the common poor man's family beverage. It might be here remarked that the license system so requisite among better regulated people, like ourselves, is unknown in those benighted countries. Wine and oil, staple articles, and forming the stock of certain shops, are sold as freely as tea and butter with us. There is no saloon or hotel bar, no treating, and though everybody drinks there is absolutely no drunkenness.

Plumbing appliances are scarce and crude, water even not being supplied into all residences—in fact it is little used except by foreigners. On the other hand, there is most extravagant abundance for fountains and cascades, perpetually flowing, and mainly through the ancient aqueducts. There being no expensive pumping plant to maintain, there are no water rates. With no frontage tax, a prince may have a street front all around his house. There being no money in supplying water to citizens, and no further power being in demand for fleecing visitors, the aqueduct promoters retired in disgust and gave up the ghost some time ago. Happy citizens.

Neatly built and well kept public conveniences, attended by females, are to be found in all public squares, parks, &c. But one very frequent convenience for men only, and to which the fastidious foreigner does not soon become acclimated, is the immodest urinal. It is a V shaped vertical niche of polished marble, perhaps 6" deep, in the walls of buildings of any kind, on the street line, not so common on the principal streets, but generally just within the entrance to all minor streets. To the ordinary Roman it makes no difference how crowded may be the sidewalk, he exercises his privilege with a clear conscience. It is a most sanitary contrivance, being always exposed, and perpetually flushed by aqueduct water. In Naples a more offensive practice is commonly indulged in by numbers of men along the curb, any time after sunset—all filth of course being removed before sunrise and the pavement flushed.

Whatever may have been the case formerly, no city could have cleaner or better paved streets, lanes, squares, &c., than the Rome of to-day—the commonest pavement being a mosaic of small, square, fine grained stones, tooth shaped, and driven down level in coarse sand. They wear to a smooth slightly convexed surface and are easily removed or reset. Everywhere this is kept perfectly clean, and stands well the traffic which is seldom heavier than carriages or omnibuses. The sewerage system is as complete as in any modern city, the "cloaca maxima" of antiquity still serving as one of the trunk sewers, and all entering into the clay colored Tiber. At London the Thames embankment of granite is a great work, but equally so, and some higher, is that of white marble lining both banks of the Tiber, with its white marble classic balustrade and frequent steps down to boat landings. The railway merely enters the city and backs out again to the switch, burrowing diagonally under the walls into a fine large station facing a beautiful public square. No nuisance is permitted from smoke, whistles, dangerous tracks, unsightly sheds, &c. The railway there does not "own the earth," but is owned and well managed by the state. Facing the station on the other side of the square, are the extensive ruins of the Baths of Diocletian, out of which have been partitioned a monastery, hospital, college, museum, a large portion of the public square and two churches, one of which was the work of Michael Angelo, who utilized the ancient granite columns as they stood, 40 feet in height.

It seems strange in this age that any city should depend on defensive walls, yet such would seem to be the case with nearly all Mediterranean cities. It is hard to realize that these peacable, kind and courteous Italians, who became a free and united nation only 25 years ago, have scarcely ever known peace during the past 25 centuries.

In all the Mediterranean countries nearly every elevation of rock, hill or mountain has its pinnacle of ruined castle, fortress or monastery. In certain cases these have continued to be inhabited within their enclosing walls, which seem to have been built to keep the houses from falling over the cliff, but probably to make it interesting for a surprise party of the neighbors. As population increased, and spread out over the plain below, new and more extended walls were built, and thus grew up walled cities, nearly all retaining the monastery within the citadel on the highest point. In one place, Orvieto for instance, as approached by rail from either direction on the plain, nothing of the city can be seen but the ancient grey stone walls, crowning the escarpment of the rock, several hundred feet above. Leaving the train and station, instead of taking a cab or bus, the traveller enters the car of an inclined railway, or "funiculaire," and is shot up through the rock tunnel under the walls and landed in a public square, then taking a cab to his hotel. Here "no architect need apply," for though "all alive," there has been no new building done for 500 years. The object of a visit here is their wonderful old cathedral, an example of early Italian gothic, the west front of which is said to be the grandest polychrome in existence, and in the blaze of the setting sun is certainly a most gorgeous spectacle.

The oldest walls of Rome, built of Tufa, without mortar, enclosed a square on the Palatine Hill. Its founder, Romulus, was nurtured by a she wolf, in a cave, still shown in this same hill. A bronze image of the wolf, partly corroded away, was found at a later date in this cave, and is preserved in the Capitoline museum, in corroboration of the legend. In later times each of the seven hills was enclosed by its separate wall, and finally all became incorporated as a happy family, within one enclosure. Portions of the ancient walls still remain. The present walls, built of stone, concrete and brick, and dating back some fifteen centuries, are about 50 feet high, 12 miles in extent, and entered through 12 gates, a few others having been walled up. The population, said at certain periods to have been two and a half millions, is now

*Paper read at the fifth annual convention of the Ontario Association of Architects.

about 350,000, or double that of Toronto. Considerable of the area is at present without buildings showing above the surface, while on the campagna, outside the walls, and without the aid of the local improvement humbug, speculative builders have ventured largely and lost all.

It is difficult to explain how the ground level has varied so much at different periods, and how so much of art and architecture has been unearthed in recent times, but there the facts are apparent, and explanations must be made to fit. The pavement of the forum and "sacra via" are some 40 feet below the level of the streets surrounding the excavations. In many cases comparatively ancient buildings stand over others that form a sort of basement, and even others as sub-basement. In the grounds of the modern residence of a prominent photographer, one can descend through three stories of an ancient palace, and this portion of the city, until recently, had been for centuries a public common. Vast stores of ancient art have, at various times, been dug up, and no doubt many times more still remain buried, to recover which would necessitate the destruction of the present city. The work of excavation is for the present at an end, and so is this paper.

THE ÆSTHETIC UNITY OF THE FINE ARTS—MORE ESPECIALLY IN RELATION TO ARCHITECTURE.*

By Hamilton MacCarthy, R.C.A.

It is only necessary to preface my remarks by saying that I address you as an artist to artists, in the broadest and most catholic sense of the term: fellow-worshippers at the shrine of the beautiful in nature, who feel their dearest ambition is to capture a ray of her glory, and crystalize it into some form of art, which may reflect its refining influence for the good and happiness of mankind, and be an incentive to virtue and noble deeds!

In speaking of architecture, it is not merely in its constructive sense of building, but the conception and creation of such edifices as claim to possess elements of grace and beauty, dignity and attractiveness, which should elevate the soul of the beholder and be a joy forever.

God created man in his own image—body, soul and spirit—and the first mental activities the primitive creature put forth were to build his rude habitation, carve ornaments on the door sills, color them with rude pigments, and chant his dirge or war song. This imitative activity was the Genesis of the arts of design: painting, architecture and sculpture, together with poetry and music—making the five sister muses of form, proportion, color, melody and rythm—the media by and through which the good and beautiful commune with the soul of man and satisfy his intellectual cravings. And are not these faculties intimately connected and associated with each other in their highest aesthetic fulfillment by some hidden mystery, not yet revealed—the principle underlying each being one and the same?

An apt figure of the five sister arts, their intimate relationship and interdependence, suggests itself to the mind in the structure and vocal organs of the human body:

1st. The skeleton—that wonderful mechanical arrangement upon which all other parts depend, combining, as it does, economy, lightness, strength and ingenuity, suggesting the building or architecture:—

2ndly. The outer covering, i.e., the muscles, giving the contour of form beauty and motion, expressed in sculpture:—

3rdly. The color and texture of the features and the skin, represented in painting.—

4thly and 5thly. Speech and vocal sound; the organs of poetry and music. Here, then, is the perfect model, set up by the Divine Architect, the synthesis of the fine arts, comprehending or embracing color, texture, form, harmony, melody, rythm and proportion—a living expression of the beautiful in mind and matter.

In the language of the immortal bard: "What a piece of work is man!—how noble in reason! how infinite in faculties! in form and moving how express and admirable! in action how like an angel! In apprehension, how like a god!—the paragon of animals."

Before leaving the masterpiece of creation, as the type or ideal model of beauty, examine for a moment his component parts: The osseous structure called the skeleton, marvel of economy and strength for the burden imposed upon it; the cranium, with its dome and arching brow, exquisite precision of sutures that join the skull; the vertebrae, ribs, pelvis, condyles of the limb bones, with their perfect ball-socket joints. Here is fitness and utility, though not necessarily beauty; yet models for the builder and mechanician in this age of steel.

It is when we consider the myology or muscles that life and beauty are apparent, and both architect and sculptor have been inspired with the perfection of form for their models. The design of the Greek and Roman mouldings is evidently in spired from the profile of the face, mouth and chin; the gently expanding and tapering columns from the limbs; the groining of the ear, chiselling of nose and nostrils, have also influenced design in architectural forms. In woman, though less powerful than man in structure, the still more graceful curves of form present a veritable incarnation of unspeakable loveliness. Thus we see form in its highest type, which receives its consummation in its texture or outer covering, the skin, the human epidermis, as seen on the cheek of a beautiful woman, combining and blending, as the painter learns, every delicate and luscious tint with the bloom and down of touch—a setting indeed for that incomparable jewel of all, the eye—the soul's window. In color and texture added to form, we reach the absolute—the highest æsthetic ideal of beauty. This trinity in unity, of color, texture, form (form including proportion), constitutes the essential and inseparable elements which the master builder has incorporated, and shows the relation and dependence of each upon the other, to express a perfect *ensemble*, each of the links being a *sine qua non* to the success of the whole; and without which neither the sculptor, painter, architect nor poet, can create his airy palaces or pourtray his themes of lore.

Bulwer well appreciated this unity in the elements of the beautiful in Claude Melnotte's description of the home to which he would take his bride could love fulfil its prayers.—"A palace lifting to eternal summers; its marble walls from out a glossy bower of coolest foliage; musical with birds, whose songs should syllable thy name. * * while the perfumed lights stole through the mists of alabaster lamps, and every air is heavy with the sighs of orange groves, and music from sweet lutes, and murmurs from low fountains that gush forth in the midst of roses!"

What is the principle in design that predominates in the human form and runs all through nature? It is a succession of curved lines of varying length, entirely free from harshness, producing to the senses a feeling of blending, melody, buoyancy and harmony.

Beauty's wave in human form,
In rose or lily, bird—
In womanhood transcends all things,
'Twas always so, I've heard!

'Twas so in ancient days, when Art
Sat graceful on her throne,
And gave her sons that curious line,
True artists love to own. —*Extract.*

*Paper read at the fifth annual convention of the Ontario Association of Architects.

The religion of the ancients required a habitation in which to worship their deities and store their *lares* and *penates*, and from the four walls of mud and wood, or brick or stone, grew the temple. Ornament, columns and capitals, were added; then the gable broke the monotony of the horizontal. Color followed. The beauty of texture was absent, till marble or an imitation filled the want. Still life was not there—human life. At length the sculptor's chisel and painter's brush filled the pediment with the deed of heroism, and enriched the walls with polychrome. Finally the temple became a work of symmetry, power and beauty; every member was studied with regard to optical value and refinement—carving, gildings and tinting drank in the glorious hues of the prism, which shone refulgent upon its harmonious proportions.

The life of action and deed of valour were implanted there in the metopes and friezes. The magnificent Quadriga and Acroterion statues adorned the angles. Caryatidae took the place of columns; finally the temple became clothed with the matchless genius of Phidias and Apelles—fit habitation indeed for the crowning glory within, the shrine of the god Zeus or Athene in Chryselephantine. Gold, ivory and precious stones; what would Homer have said had he seen these wonderful achievements in Art.

It was centuries before, he sang of the god:

"He said and nodded with his shadowy brows;
Waved on the immortal head the ambrosial locks,
And all Olympus trembled at his nod."

Remember, it was not the intrinsic value of the material that made the masterpiece. Its value lay in its incomparable embodiment of benign beauty and sublime expression. The genius of Phidias, appreciating the importance of aesthetic unity, at once saw that even marble failed, beautiful as it was, to fulfil the highest ideal of texture as representing the flesh, and so chose ivory—which of all material bears the closest resemblance to the human epidermis. White marble is beautiful when fresh from the chisel, but without great care soils and loses its appearance, till old age or time has turned it into the color of ivory, like the Venus de Milo in her hallowed shrine in the Louvre, or the memorials of old-gold hue such as are seen in Westminster Abbey, or the Elgin marbles from the Parthenon and now in the British museum—the latter cut 438 B.C.

The true artist or dilletanti, who has drank the nectar from those gods of form and beauty, Phidias, Myron, Scopas, Polycleitus, Praxiteles, and others of the age of Pericles, can only contemplate their works with wonder and fascination at the supreme mastery gained by these sculptors of the human form over their art, yet mingled with regret that so few examples have escaped the bands of the iconoclast and the ravages of war.

We who have worshipped at the feet of Hermes, Aphodite, the Discobolus, the Gladiator or the Illisus, or the other masterpieces that adorn the Parthenon, feel that this is not the occasion to enter upon the various merits of the works of those great artists. They have been of incalculable value to art and history. They tell the story of their age. We acknowledge them to be the absolute and immutable standards of physical beauty; the ideals for the artists and dilletanti of the world.

The pediment of sculpture expresses at once grandeur, power and life, and it is to be regretted that architects of the Victorian era have not been more inspired with the use and possibilities of statuary—the most profound and longest enduring form of Art—especially in connection with public buildings and monuments, in which the nation's history should be indelibly written.

And how have we of the 18th and 19th centuries treated the classic orders? These forms of architecture have been largely used for public buildings, both in Great Britain and America, but what relation have they borne to their ancient prototypes? Where are the sculptured pediment, frieze and metopes of beauty and action, once instinct with life and imagery?—the tinted walls and colored story? They have departed; the sheen of the rainbow has gone from the classic mouldings; texture of marble, mosaics, encaustic and polychrome, all, omitted; Phidias and Apelles are banished; the temple has fallen. The diadem has been torn from her brow, the jewel from her breast—the robe of beauty replaced by sackcloth and ashes. The skeleton alone, in dingy grav or blackened stone, is all that remains to us moderns to help us to imagine we are beholding a noble Greek or Roman columniar edifice, and to enthuse about. Surely an anachronism in art!

With the extravagance and luxury of Imperial Rome, the purity and beauty of Greek sculpture were lost, and with Rome's final destruction all art was extinguished, except that of the monks.

From the Byzantine and the Basilica evolved the Gothic, an entirely new departure. No doubt the minaret was the progenitor or archetype of the spire and tower; but the principle underlying this remarkable revolution from an æsthetic point of view was the overthrow of the rectangular in art. The temple, shorn of its sculpture and color, is heavy, uninteresting and depressing, and its minor ornaments, though chaste, are monotonous and severe.

Both in plan and elevation, the disposition of the masses of material in the Gothic, being modelled more after nature's ideal of form, is a blending of harmonious lines pleasing to the eye. There's nothing in nature suggestive of the rectangular. The luxuriant plant-life ornament of the early English; the clustered columns; trefoil tracery; graceful arches and groined chapels; those lofty spires seemed to break through the burden of earthly cares, and carry up with them like incense the prayers of the Christian in worship of the true God to the very feet of heaven. "Lift up your heads, oh ye gates! and the glory shall come in." This was the spiritual significance of the Gothic; and it became clothed with at least earthly glory.

Color and texture were added to form.—Marbles of every tint, mural paintings, mosaics, the sculptured niche and statues—everything that wealth and art could bestow to render the habitation of God a dream of heavenly beauty. "Gloria in Excelsis Deo."

In the revival of art and learning in Italy, sculpture and painting again took their place as a power in the world. Aesthetic unity and harmony of design were insured and rendered more potent by the fact that in so many instances, painting, sculpture and architecture were combined in the work of the same artist.

The Florentines were quick to appreciate and express their joy on the dawn of renewed artistic life. When Cimabue first taught the world to paint anew, Florence proclaimed a public holiday in honor of his masterpiece, for S. Maria Novello. Nicola Persano, Giotto, Brunellischi, Donatello, Della Robbia, Ghiberti and other architects, painters and sculptors—the progenitors of the Renaissance—brought their genius and devotion to bring about the fuller perfection which culminated in Raphael, Correggio, Da Vinci and Michael Angelo—the four pillars or archangels of that great epoch of art—and terminated in Celleni, Tintoretto, Titian and Paul Veronese, masterful exemplars of the mundane magnificence of Venice.

The Italian revival affected the purity of Hellenic form, but it accomplished something greater;—it pourtrayed not merely the perfection of sensuous beauty in the form, or sublime grandeur of the gods—the teachings of Christ were expressed in human sympathy and love, devotion and adoration, at the gift of God in his son, and the struggles and throes through which man is passing to attain eternal life. What a joyous note of hope,

of harmony, of sentiment, of love and adoration was theirs—Persano, Giotto, Donatello, Della Robbia, Ghiberti!

Religious faith was the stimulus which inspired their genius and devotion. How much is art indebted to these sculptors of the early Renaissance!

In the conception of a noble edifice, the architect has crossed the border line of a mere building—i.e., a huge cube with holes to admit light and entrance—and entered the domain of the painter and sculptor. Form, in its first stage, viz., the handling and arranging into harmony of the gross masses or masonry, so as to bring about the greatest effect of beauty and proportion; realizing a noble outline or form in the gross. The carver must now join him in decorative enrichments to make the work interesting and repay closer inspection—form in detail or abstract; still only ornament. The sculptor then takes him to a higher plane, with emblematic or symbolic figures, in *basso* or *alto relievo*, or round attached form in transition, in which the walls gently breathe the story or mind of the building, its history or purpose. No form of art is more profound, than these children of the mist emerging from fancy into reality—form in the first stage of statuary.

Every building of importance should be treated in this way, and would therefore be an object lesson and work of interest forever, not only to those who see it many times—perhaps every day of their lives—but also to the stranger; the most emphatic record of civic or national achievements, events or progress.

The Reformation gave the death knell to sculpture and ornamentation for a time in Protestant countries, till a church became bereft of all beauty. The Gothic was treated similarly to the Classic—shorn of its art—the shell only remaining, and all art suffered in consequence.

How sad it is to look upon our cathedrals in brick—not in form, but, alas,—in texture and color. It is only during the last quarter of this century that we are beginning to awake from this iconoclastic superstition and believe that we can worship God "in spirit and in truth," and at the same time beautify his house with tinted walls and stained glass, and other decorations.

Freedom and toleration are the spirit of the age, and the impulse in art is to discover something new and best adapted to our surroundings. In architecture we are in a state of transition, if not of chaos, and in danger of degenerating into confusion and ugliness. It is this critical stage that affords the opportunity for our architects to create a style that, while retaining all that is beautiful in the heritage of the past, will meet the requirements of the climate, and be distinctly national in character, ornament and expression.

Form is the first element of the beautiful in aesthetics, and influences everything we see and hear in nature and art, from the throat of a nightingale or a Patti, the melody of a Stradevarius, to the acoustics of a building, and should be the object of study from the lowest step to the highest pinnacle of a structure. In a wider sense it also affects the laying out of streets, parks, squares and gardens; the selection of a site, the raised plateau or eminence, grandeur upon which important edifices may be erected; the fountain, steps and terraced walk, with sculptured vases and ideal statuary, such as we see at the Crystal Palace, Versailles, the Tuilleries Gardens or in Edinburgh. All are form, perceptible to sight and touch, and instinct with life and power to give us joy and elevate our souls, improve our manners and relieve our daily burthens.

The modern Romanesque does not impress you with a sense of grandeur or beauty. Its basket-work ornament, unlike the longer and more graceful Gothic plant life, is indefinite and confusing, and with the horrible heads of animals called "grotesque," is barbarous. It no doubt originated in the early stages of inability to imitate life better. It is unfit for a woman to look upon, and should be banished from the front, or any part of a building where the lesson of beauty should be presented. There is a place for the conventional—but as little of it as possible. The lamp of truth in art has been extinguished so many times by wars and puritanism, that form still goes on crutches in the respect of carving and sculpture.

Foliage, fruit, flowers and other imitations of organic objects, should keep as close to nature as possible, to be of interest, due regard being paid to the nature of the material employed. Organic nature should be more largely drawn from for objects of ornament, and executed in the fulness of its natural beauty. The divine sculptor has furnished us with many noble and beautiful examples for imitation, to wit—the lion, the lion, the tiger, the horse, the ox, the ram, the hound, the deer and gazelle; the eagle, the swan, the dove and other birds; the dolphin, the nautilus, and other denizens of the deep. Many of these are symbolic; all are grand or beautiful, and as ornament in appropriate positions, would be of far greater interest than conventional scrolls, and serve to remind us of the wonders of nature.

The higher stages of sculpture proper, viz., figure subjects in relief and the statue, or group in the round form, may be termed the "lamp of life," and provision should be made for each of these forms in every building which claims to be a work of architecture. The relief has been described as the shibboleth or watchword of art, and has a philosophy peculiarly its own. It is specially adapted for emblematic figures, filling spaces in the architecture, and for special subjects in the history of the institution to which the building is dedicated, on the exterior or in positions where painting is undesirable.

The entrance and inner halls, vestibule and staircase, are suitable for natural or emblematic statuary, brackets for busts, and niches for statues of the genus loci, founder or benefactor, care being taken by the architect that light is provided at a suitable angle for both night and day.

The highest stage of sculpture has no necessary connection with a building, unless from local circumstances. It is reached in either the group or solitary figure, expressing an abstract motif, an emotion or passion, or any of the higher attributes of our being, or the elements of nature which may bear personification, or in national monuments where philanthropy, statesmanship or patriotism are commemorated.

The next important member of the æsthetic trinity is color, and when we consider the share this element occupies in the book of nature—how generously the Almighty has decked his creatures—whether our wondering upturned eyes gaze into the infinite azure of the brave o'erhanging firmament, fretted with golden fire; the jasper of the vasty deep; the carnation of the rose; the pallor or orange of the lily—each with its spiritual significance and relation to form and sound—we recognize at once the length and depth and breadth of his boundless generosity in this particular gift, and we marvel how it can be possible that in the 19th century, man should, even in his most joyous and festive moments, clo he himself in black from head to foot—a color that is always alluded to in terms of horror and associated with our worst enemy, and one that is the least seen in nature's kaleidescope.

Color is nature's life and light and joy-giver, and when its presence is withheld from us, our spirits are in like measure deppressed. To speak of her riches requires the rhapsody of the poet; to comprehend her glory, the eye and wings of the eagle, to carry us to the floor of heaven. The painter is privileged to penetrate her hidden mysteries and capture the fleeting subtleties of her ever-changing moods.

In architecture, the scheme of color decoration should receive the most careful consideration, and be in relation and conjunction with the carving and ornament in form. In all important buildings spaces should be provided in the halls, staircase and ceilings, arches and domes, for special frescoes by artists of ability, affording opportunity for tableaux of prominent incidents or scenes in the life of the country, in alliance with the objects of the building. By this means the skill of our eminent painters could be utilized for the education, happiness and intellectual enjoyment of the people. Stained glass, mosaic, furnishing and lighting, should all be included in the one scheme of design, and require the same mind and care in their use—the cardinal virtue of all decoration being strictly observed, viz., the securing of cluster and space, and repose, so essential in art.

In order to effect a complete aesthetic harmony, texture—its substance, or rather, material—has to be considered, which, of course, is involved so largely in color that the one can hardly be discussed without the other, bearing, as it does, the same relation to form as form does to sound. The ancients saw the importance of producing color and texture, and where costly marbles could not be procured, the artificial substitute approaching as nearly as possible to the semi-transparent beauty of marble was provided. Stone is the next best material, especially for carving, but cannot be relied upon to stand climatic influences, besides not fulfilling the highest aesthetic requirements. Brick, as it has been used, is an abomination, but we are glad to see improvements taking place in its manufacture. Greater size and neutrality of color, combined with a soft or egg-shell glaze, may render it much more acceptable. Under this head I may mention a material which, now existing, but not in general use, having all the beauty of texture and colors of marble, is not affected by climate.

In the brief remarks the present opportunity has afforded me, I have endeavored to show the important place *Form* occupies in the elements of the beautiful, especially in its pre-eminent phases of architecture and sculpture, and the influence it must have upon the dignity and attractiveness of a city of learning, art and culture, and as the medium of expression of a nation illustrious in noble deeds and beneficence; yet I feel the fringe only of the subject has been approached.

Before concluding this paper, I venture to call attention to two or three matters seriously affecting the beauty of our city, and which constitute an outrage to good taste and common sense:

1st. The dangerous and unsightly trolley, telephone and electric light poles, wires, &c., which should never have been erected in a city like Toronto.

2nd. The want of public squares, tastefully laid out. The objectionable mode of taxing lawns at the side of residences.

3rd. The disposition to build up our principal corners to an angle instead of to an octagon or circus.

4th. We are now erecting municipal buildings of a costly character, and if the system of building without regard to beauty is allowed to continue, the view as you ascend Bay street will be narrowed, and the Court House dwarfed by some enterprising merchants. Such a course would be worse than a blunder, and should not be allowed to take place at any price.

Many other points in connection with the aesthetic welfare of our city demand immediate attention. What is required to prevent future mistakes, and perhaps rectify past errors, is the appointment of some central authority, such as a City Architect or Minister of Public Works, to prevent the erection of unsightly buildings, and preserve important open places as gardens. Such a person or board of control should be appointed for their known taste and abilities, and they should be backed up by an association of dilletanti, both professional and lay, who would carefully guard the aesthetic interests of the city, and render it the pride of her inhabitants, the admiration of its visitors and the envy of other cities.

Brethren in Art—As the genii and guardians of the beautiful, in all that concerns the artistic progress of your country, and the cities in which you dwell, you are called upon to devote your talents, your love and your watchfulness to her service; to bind yourselves together in the Brotherhood of Art, for her defence; for the vanquishment of the Philistine and the Philistian; for the prevention of errors and incongruities, outrages to taste and beauty, frequently occurring, and which now threaten irreparable injury to the few remaining places of interest in this city; that you apply your genius to the development of a distinctly Canadian Architecture, suitable to the conditions of the country, and upon which shall be implanted in sculpture and painting, the romance and lore of her history, the valour of her sons, the beauty of her daughters and the industry and resources of her people, together with the picturesque grandeur of your scenery and skies—notes of harmony and patriotism, which shall shed lustre upon your country, inspire the poet, the musician and the historian, and earn for yourselves a niche in the eternal temple of fame.

DISCUSSION.

The President said he felt we all must have greatly enjoyed Mr. MacCarthy's admirable paper. He thought the range of subject matter in the papers read at the present convention showed the great scope of the architectural profession.

Mr. Aylsworth said no doubt the members were being educated as architects and artists, but something further was needed. He would ask, are the people at large being educated as fast as they might be to a higher degree of artistic taste? Until there prevailed a sentiment of patriotism among the people it was useless to look for the production of grand public buildings, nor without a national religious feeling could be expected noble temples such as were to be found in other lands. In his reading he had come across an extract which he would like to read. It would have been a source of great satisfaction could he have told the Convention that it emanated from the City Council of Toronto, but truth compelled him to say that it came from the archives of the city of Florence, and it was some 600 years old. It would explain to a certain extent how the durable and magnificent buildings which delighted the eye of the traveller in older lands than our own, came into existence. It was the decision of what in our days would be called the Council, after the destruction of one of the Florentine churches:

"Whereas, it is of the highest interest to a people of illustrious origin, so to proceed in their affairs that men may perceive from their external works that their designs were at once wise and magnanimous; it is therefore ordered that Arnolfo, Architect of our Commune, prepare a model or design for the rebuilding of Santa Reparta, with such supreme and lavish magnificence that neither the industry nor the capacity of man shall be able to devise anything more grand or more beautiful; inasmuch as the most judicious in this city have pronounced the opinion in public and private conferences that no work of the commune should be undertaken unless the design be to make it correspondent with a heart which is of the greatest nature, because composed of the spirit of many citizens united together in one single will."

CORRESPONDENCE.

Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

EFFECT OF AMERICAN DRAINAGE WORKS ON CANADIAN INTERESTS.

QUEBEC, March 3rd, 1895.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—When I wrote you in January last, as to my surprise that our Dominion Parliament had allowed a franchise to be given by Congress without its consent, to rob our Canadian head waters of some 3½ per cent. to supplement the requirements of the Chicago drainage works on their way towards the Gulf of Mexico, I did not think that our winking at such a thing would embolden another company to so soon petition the United States Senate for an act of incorporation, with a $100,000,000 capital, to again tap the lakes in one or more than one point for commercial purposes, running towards the Hudson and New York en route for the Atlantic.

Such, however, is the case. The bill is before the U. S. Senate, and will of course go through like the Chicago bill, if no stand be taken against its becoming law.

I showed how the present capacity of the Chicago outflow towards the Mississippi is, or will be, when the drainage works are completed in 1896, not less than 1-30 or 3⅓ per cent. of the feed waters of the St. Lawrence, and how this percentage may in a few years be increased to 10, if Chicago continues to grow as it has done during the past few years.

Now each of the proposed canals of the "American Maritime Canal Co." may take, not only 10 per cent. or twenty, of our waters, but even thirty, and three such tappings would suffice to withdraw the whole of the water at present flowing over Niagara from Erie to Ontario—reducing the St. Lawrence below Niagara to the drainage of the valley of the Ontario and the water brought down by the Ottawa, the St. Maurice and other tributaries.

It may be, sir, that, as interested in Quebec, I am cutting my own throat in calling attention to this matter, as the less the flow the less the depth in Lake St. Peter, the better the excuse for ocean vessels not going to Montreal, and remaining here where we have the advantage of tide waters to cover the deficiency twice in every twenty-four hours; but, sir, I take a broader view of this matter, and look to the interests of Canada in general, of the Dominion at large, and I can conceive nothing more cool than for our neighbors beyond the line of 49, thus to attempt to rob us of our God-given patrimony, with our engineers, our legislature, looking on in utter indifference to an act of spoliation which certainly has no parallel among civilized nations.

C. BAILLARGÉ,
Member C. Ass. C. E., City Engineer, Quebec.

DEPARTMENTAL STORE BUILDINGS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The attempts which are being made to stem the tide of modern progress in the direction of large departmental stores will be in vain, but in one way these stores as built or altered become a menace to the safety of the surrounding community, which should not be tolerated, and which it is in the power of the community to control.

Owing to the extensive floor areas demanded for attractive display or for easy supervision, and the heaps of inflammable goods and fixtures, they are peculiarly liable to a sort of galloping consumption which seems to be epidemic in Toronto this winter.

The destruction of the new Simpson building and the attendant losses to surrounding owners, besides the expense to the city generally, is not only to be lamented, but becomes an outrage that ought to be resented, because unnecessary and preventible.

In all municipal building regulations the danger of large undivided floor areas is recognized and prohibited. Our own building by-laws require brick party walls at certain distances, limiting the floor areas, but these commercial barons do not readily submit to such wholesome restriction. They build or alter their airy castles to suit their own ideas of trade, their helpless neighbors, including the municipal burghers, meekly submitting just as to the warlike barons of old.

Now in no other class of buildings should these regulations be more strictly enforced. Let there be frequent party walls running from basement to roof, though having ample openings for display and circulation, readily closed by sliding or rolling fireproof doors. This need be no hardship, and trade would easily accommodate itself to such a requirement. Besides this, no building above the reach of water by the ordinary appliances should be permitted, unless fire-proof or fire-resisting throughout. The slight additional cost would be little enough penalty for erecting such tasteless structures, so unsymmetrical, in our streets, and so damaging to their more modest competitors.

The Simpson building was the best representative of its class in the city, a style of temple expressly designed to meet the demands of the modern mammon worshipper—the greatest display in the slenderest building. The architect deserves credit for the triumph obtained for his employer—a strong building with the minimum of space occupied by supports, and faultless in exterior detail.

But such a building is neither fire-proof nor fire-resisting; it assists the spread of the flames, it is dangerous to firemen, to inmates and to surrounding property. The new building was not only an unbroken space, but the walls of the older portions were removed to extend the view. What happened here is most likely to happen at different points in the city. Such a fire may prove a great advertisement to the large store, but no such good luck to the neighboring small fry, who are more likely to be injured by its competition and ruined by its destruction.

In all probability the phoenix will rise, a greater menace than before. If there were no remedy there might be some virtue in a calm resignation; or even if there were only the expensive method of fire-proofing, the choice of the cheaper method might be excusable. But there are a number of building methods, inexpensive, yet far superior to that now becoming so popular. The party wall of the Buntin Reid building, in stopping our second great fire, gave proof of its utility and economy. Floors and roofs might quite easily be made fire-proof at a moderate cost in more than one manner.

For the present a hint only is thrown out, but in a later issue may be given some description, showing that we need not suffer so extensively from fire if we choose to resist it.

Yours, &c.,
M. B. AYLESWORTH.

TORONTO MASTER PLUMBERS' ASSOCIATION.

FOLLOWING are the officers elect of the above Association for the ensuing year: President, Thos. Cook; first vice-president, W. J. Burroughes; second vice-president, Geo. Guest; secretary, J. K. Alison; treasurer, A. Fiddes; sergeant-at-arms, Walter J. Garratt. A Sanitary Committee was appointed; likewise a Committee to endeavor to secure a reduction of the license fee from $10 to $1 per annum.

Ontario Association of Architects

IT is intended, as agreed at the recent Convention of the Association, to give a diploma to students who have already passed and to those who will hereafter pass the final examination of the Association.

In order that a design may be obtained suitable for the purpose and worthy of the Association, members and students are asked to offer drawings. They should be prepared for photographic reproduction. The design to occupy a space 8 inches vertical by 14 inches horizontal, with a three inch margin all round in addition. The verbal matter is to be as follows:—

THE ONTARIO ASSOCIATION OF ARCHITECTS.

This is to certify that—. . . . . .

has passed the qualifying examinations required by the Ontario Architects' Act and is entitled to be enrolled as a member of the Ontario Association of Architects, and thereafter to practice as an architect in the Province of Ontario.

Dated at Toronto this day of 18

. . . . . : . *President.*
. . . . . *Registrar.*

There must be space at the bottom for the seal of the Association, which is 2½ inches in diameter, to be set on the left of the signatures of the President and Registrar.

Drawings are requested to be sent to W. A. Langton, Registrar, Canada Life Building, Toronto, not later than May 1st next.

NORWICH

Folded Paper Floor Deafener

PATENTED

Advantages:
CHEAPNESS,
CLEANLINESS,
EVENNESS,
LIGHTNESS OF WEIGHT AND RAPIDITY WITH WHICH IT MAY BE HANDLED

For Sheeting and Deafening in Houses, Offices, Buildings, etc. Insulating Cold Storage Warehouses, Refrigerators and Ice Houses.

OUR new **Patent Folded Paper Floor Deafener** is the most practical and common sense DEAFENER ever placed between double floors, on account of its peculiar construction forming air chambers, which makes the best deafener known. It is just coming into use and has already been tested by a number of Architects, from whom a number of testimonials were sent unsolicited on our part.

If you have an opportunity to use a deafener, we trust you will give this a trial, as we can assure you it will be no experiment if used properly. Our regular Carpet Lining will not answer for this purpose, so be sure the deafener is used, and not the Carpet Lining, in contracts where our DEAFENER is called for.

It is put up in rolls of 450 square feet, each 36 inches wide, and can be supplied at the factory or bought from our agents at one cent per square foot.

Any other information you may wish in regard to the material will be gladly furnished upon application to

Royal Cement Plaster

Rightfully the king of all plasters.
Only absolutely perfect natural plastering material.
Your house plastered with it will be warmer in winter and cooler in summer.
As freezing does not affect it after once set, can be safely used during the winter.
Literally harder and more dense than rock, therefore impenetrable to rats, vermin and disease germs.

Costs but little more than mortar work.
Enables a building to be occupied almost immediately, saving weeks.
Manufactured so accurately that skilled labor not necessary to insure perfect work.
Easily applied by any mechanic and produces a wall hard, strong and thoroughly fire-proof.
Not a patent material made from plaster paris, glue, acids and other unhealthy compounds.
Thoroughly pure and perfect in its natural state, absolutely no ingredients used in its manufacture.

Prices made for delivery at any point.
Liberal inducements offered and satisfaction guaranteed.
All of our material is positively perfect, otherwise no payment expected.
Security, protection and profit assured our agents and customers in every respect.
This material works easy under the trowel and is slow setting, thereby preventing all waste.
Entire avoidance of cracks, bulges and other customary defects by its use.
ROYAL in name, **CEMENT** by nature, **PLASTER** its purpose.

THE Master Plumbers' Association of Toronto have petitioned the City Council to amend in several important particulars the plumbing by-law of the city. They ask that the license fee be reduced from $10 to $1 per year; that a qualifying examination must be passed by every person to whom a license is granted; that a permit to construct or reconstruct the drainage system of any building shall issue to the master plumber only. The City Engineer recommends the Council to refuse to reduce the license fee, to grant the petition for a qualifying examination, and in lieu of granting an exclusive permit to the plumber, to so amend the by-law as to prohibit the laying of tile drains under dwellings, and to substitute therefor iron pipes, to be put in and connected with the drains outside the house by the licensed plumbers only, which would enable the plumber's work to be inspected and a certificate issued independent of the drain layers, which, at present, is one of the difficulties of carrying out the existing plumbing by-law. It is hoped that the Council will see the wisdom of adopting these and other required amendments to the by-law. The master plumbers have suffered the injustice of being compelled to pay a license fee of $10 per year for the privilege of doing business in competition with carpenters, tinsmiths, and everybody else who might see fit to take out a plumber's license, as the by-law does not provide that applicants for license must undergo examination. The absence of such a provision has thrown a large amount of plumbing work which should properly belong to the qualified master plumber, into the hands of journeymen, apprentices and persons in other lines of business who saw a chance to make a profit above the cost of the license by tacking on plumbing as a side line to their legitimate business. The by-law should fix the lowest limit of weight of iron pipe at 12 or 13 pounds to the foot, as it is frequently the case with cast iron pipe that one side is much thinner than the other, and in pipe weighing but nine pounds to the foot, a very slight indentation is sometimes sufficient to puncture the metal on the thin side, while it is with difficulty that joints can be made tight without cracking the pipe. It is the opinion of persons who have followed closely developments in sanitary science that at least in the newer sections of the city, where the sewers are in good condition, the trap and breather which the present by-law specifies shall be attached to the house-drain between the building and the sewer should be abolished, and the soil pipes allowed to act as ventilators for the sewers. It is a well-known fact that for two or three months during a severe winter, such as we have just passed through, the street gratings, which are designed to act as ventilators for the sewers, become choked with snow and ice, and sewers and drains leading therefrom are charged with foul gases, which, were iron drains employed, and outside traps and breathers omitted, would be carried through the house-drains and discharged into the atmosphere above the roof. In recent amendments to the New York plumbing regulations, the use of the outside trap and breather is made optional, and in practice their employment is said to be declining.

THE Committee of the Ontario Association of Architects appointed to recommend to the City Council required amendments to the Toronto Building By-law, have completed their work. The Committee have given their most careful consideration to the subject, and have presented to the Council a draft by-law embodying what they believe to be necessary. The matter will shortly receive consideration at the hands of the Council. The O. A. A., as well as the Special Committee who have had the matter in hand, have rendered a valuable service which the Council and public should not fail to recognize.

WE regret to learn that the exhibition of architectural drawings under the exclusive direction of the O.A.A., which it was announced in our March issue would form a distinctive feature of the sixteenth annual exhibition of the Royal Canadian Academy, will have to be foregone. As the result, it is said, of representations on the part of some of its members, the Academy has seen fit to withdraw its permission to allow the architectural drawings to occupy a separate room at the Exhibition and to be hung under the direction of a special committee appointed by the O. A. A. This decision will to a large extent destroy the advantage which it was hoped might accrue to Canadian architects as the result of public attention being drawn to a carefully arranged exhibit of their work.

IN the preparations now in progress for the erection of new buildings to take the place of some of those destroyed in the recent Toronto fires, contractors have had their ingenuity exercised and been put to considerable expense in pulling down the brick walls, chimneys, etc., which stood their ground after the more combustible materials had been devoured by the flames. In this connection our attention has been drawn to the fact that when work of this character is required to be done in Great Britain, permission is asked by the authorities of the engineering schools to be allowed to perform it free of charge, as an object lesson for their students. The practice is one which might with advantage be adopted by Canadian engineering and technical schools. It would no doubt work to the benefit of both students and contractors.

THE Society of Architects of London, resolved at a general meeting held last October, that after the 1st of November next, applicants for membership in the Society be required to pass an examination to show proof of qualification. The subjects of the first examination are as follows:—Architectural History: The general principles of the various styles and periods of architecture; their dates, mouldings and enrichments. Planning and design: The plan and design of some building, or portion of a building, with details to a larger scale. Construction: Constructional details in all trades. Materials: The properties, methods of working, manufacture, and the application of materials to building works. Specifications: Preparation of specifications, and the examination of builder's accounts. Contracts: The conditions pertaining to a building contract; the relative position of architect, client and contractor; and other questions of ordinary practice. Sanitary Science: To include water supply and drainage, ventilation, lighting and heating of buildings.

THE ONTARIO ARCHITECTS' BILL.

THE Act to amend the Ontario Architects' Act, prepared by the Council of the Ontario Association of Architects, and introduced at the recent session of the Ontario Legislature by Mr. O. A. Howland, M. P. P., has shared the lot of many other bills at the close of the session, in not having been reached for a second reading before the House prorogued. Good progress, however, has been made by the Registrar, Mr. W. A. Langton, and his associates, who were engaged in promoting the bill, and it is hardly anticipating too much to say, that it stands a reasonable chance of becoming law at the next session of the legislature.

Much of the doubt that surrounded the measure has disappeared. Having passed the first reading, Mr. Langton and his committee pursued the intelligent and convincing policy of bringing the principles of the bill before leading members of the House. The general impression had been that the bill was of an exclusive and monopolistic character, but a careful study of its main clauses sufficed to show, even leaders of the Patron Party, that there was nothing objectionable asked for in the bill. The important point aimed at is to make the degree of architect hold a parallel place with an M. A. or other educational degree.

There is nothing suggested that would bar out any person now practising architecture within the province from becoming a member of the Ontario Association of Architects were the new bill now law. On the contrary, it specially provides that any such person "by causing his name to be registered with the registrar of the Association within three months from the coming into force of this Act, and by paying to the registrar such fee as may be made payable in that behalf," becomes a registered architect under the proposed Act. The bill further provides, that in case any such person omits to be registered within the said period of three months through absence, illness or inadvertence, he is not necessarily prevented from qualifying under the Act, but at the discretion of the Council he may be admitted to enrollment.

The impression has prevailed, in some circles, that were the Act to become law builders and others would be prevented from undertaking the execution of plans for those who might prefer to place the work with them, rather than with a registered architect. This is not the case. If any person thinks that an architect's fees are too high, or for any other reason does not wish to engage his services to prepare plans for a building, the contractor who would construct the building can prepare the plans. This contractor may call himself by whatever name he likes, save that he does not announce himself as an architect. The thorough understanding of this clause by the members of the Legislature, and especially the Patrons, has done a good deal to remove objection to the bill. Some had thought that the farmer or other resident of a rural section, who might want a barn built, or farm house enlarged, would be compelled to engage the services of a registered architect, just as he would look to a barrister for a settlement of any point of litigation, or to a doctor to cure some of his bodily ailments.

Where objection has been taken to the bill in the past lest extortionate fees should be imposed by the Council of the Ontario Association of Architects, the bill as introduced by Mr. Howland leaves the fixing of the fees to the Lieutenant-Governor-in-Council, and shall be for the following purposes only:

A—For registration as a student.
B—For each assignment of articles.
C—For each examination.
D—For registration as an architect.
E—For the annual fees of members.

The qualification for registration is, that "the applicant shall be not less than twenty-one years of age and shall have served as a student not less than five years with a principal or principals entitled to registration under this Act or with any other principal or principals, whether resident or practising in Canada or elsewhere, approved by the Council and shall have passed such qualifying examinations as may be required by this Act." The concession is made that any person that has graduated from the Ontario School of Practical Science shall be required to serve only three years as a student, one of which three years may be served during the vacation of the school.

The Act, in fact, is an educational measure, pure and simple, designed to raise the standard of the architectural profession. Architects' bills have sometimes been referred to as legislation for architects, rather than legislation for architecture. The present bill is one in which this criticism has no application. It is legislation for architecture—the cause, not the individual. In an age when the disposition is towards scamp work, and a lack of thoroughness prevails to a large extent in all callings, architects and builders alike would, we fancy, welcome any measure that has for its purpose the raising of the standard of work done.

The local Board of Health of the city of Kingston urges the City Council to appoint an Inspector of Plumbing.

The Toronto Public Library has recently received through the Secretary of State, from H. H. the Maharajah of Jeypore, a set of seven volumes on Indian Architecture. The work will form a valuable addition to the already interesting collection of architectural books to be found in the Toronto library.

SAWING STONE BY WIND POWER.

MR. JOHN KLINE, jr., of Halifax, Nova Scotia, is the owner of a stone sawing mill which enjoys the unique distinction of being the only mill of the kind in America operated by wind power. Mr. Kline furnishes Stone with the following data:—

Mr. Kline's principal reason for adopting this kind of power was because fuel is quite expensive in Nova Scotia, notwithstanding it is a coal-producing country, and further, because with this power he could let his mill run windy nights with less attention—the wind in that region being of a more uniformly steady character than in the lower countries of the temperate zone. Thus a material saving is effected over steam power and a larger production is assured. The wheel adopted is 16 feet in diameter. It runs a gang of three blades in excellent shape under a light breeze. Mr. Kline figures out a positive saving over steam of three dollars a day, not counting his saving in labor, and the mill is yet an experimental one in the application of the most modern machinery for sawing stone. The mill is set to saw 1½ inches per hour, in granite, and it is doing the work splendidly. It is guaranteed to furnish sufficient power under an ordinary wind, say one of five to eight miles an hour velocity, to cut three inches an hour in the hardest granite, using crushed steel for feed to the saws. The machine works true and is under regulation to any speed desired in any wind less than a tempest.

In connection with this brief allusion to a novel mill for sawing stone Mr. Kline writes interestingly of other matters relating to the trade in the Province. He says: "You will be surprised, no doubt, when you learn that of the boundless quantity of good granite and building stone, to be found in Nova Scotia, that so little of it is produced for use in building our towns and cities. The cost of working granite is so high that large contracts are rarely made. Being the largest producer and manufacturer in the Province, and the only one using steam power, I have been involved in the labor question more largely than others, and in efforts to popularize the use of granite have been at a disadvantage on that account. Some years ago I had the price of granite within the reach of any one disposed to use it, and had taken a large contract, when the cutters formed a union and advanced wages 50 per cent. and demanded that the granite be brought to Halifax in the rough and cut there, my quarries being about three miles away. The masons and bricklayers joined the cutters and boycotted my granite. I employed non-union cutters, but am debarred from handling any dressed stone for buildings in the city. In consequence the demand for the material has lessened, I am poorer in purse, the contractors get fewer contracts for granite and stone buildings, and a great many of the striking cutters have had to go to other places and work ten hours a day for 25 cents an hour. I pay two to three dollars a day of ten hours, according to the skill of the workman, and they have steady work the year round, but the jobs are not on Halifax Buildings.

"We get between four and five dollars a ton for rough granite delivered in the city. The amount of granite handled in Halifax in one year is about 2,000 tons, mostly for street purposes. I export largely. You will wonder when I tell you that I have sent granite to Aberdeen, but it is true. I have an order from there for a large cargo of granite, samples of which I have sent to you, and which is taken from a quarry in Annapolis county. I get for a block containing 36 cubic feet $23 a ton in Aberdeen. For smaller blocks the price at that city is about 65 cents a cubic foot; the average rate is fair, and much better than we get in Halifax.

"Our excellent granites could be produced and exported at a reasonable profit if capitalists would become interested in developing them. I have an arrangement with shippers here to take any quantity from five to a hundred tons at a time, so there is no necessity for me yarding stock for shipment."

Mr. Kline intends to equip his wind power mill with the latest improved machinery, and to test the full capacity of the windmill as a prime mover in the manufacture of stone.

THE officers elect of the Contractors' and Builders' Association of Ottawa, are as follows: President, John A. Askworth; first vice-president, John McKinley; second vice-president, Joseph Gravelle; recording secretary, James Bennett; assistant recording secretary, H. Burgess; treasurer, E. B. Butterworth.

PERSONAL.

Mr. W. P. Witton has commenced the practice of architecture at No. 24 James Street South, Hamilton, Ont.

Mr. Thomas Tompkins, contractor, of Brockville, Ont., has recently returned from an extended trip to Australia and New Zealand.

Mr. S. G. Curry, ex-President of the Ontario Association of Architects, has resumed the practice of his profession in Toronto, having opened an office at No. 70 Victoria Street.

Mr. George Browne, architect, of Winnipeg, who spent the greater part of the winter in Ontario, has returned to the Northwest; but expresses his intention to remove to New York City at the close of the present year.

Mr. H. C. McBride, of London, Ont., was in the city a few days ago. He will superintend the erection of the new Queen's Avenue Methodist Church, the plans for which are being prepared by Mr. Edmund Burke. Mr. McBride reports a fair outlook for building operations in the Forest City, this season.

VENTILATION A FEATURE.

THE builder of houses a few years ago was expected to introduce a warming plant only, with ventilation a thing unheard of practically; to-day he must not only warm the house, but must successfully ventilate it, and the same is true in buildings of all kinds. Ventilation is now bought and sold as much as the warming plant, and the manufacturer of furnaces and warming plants who cannot demonstrate his ability to ventilate well must expect to lose all contracts

The business of house-heating has developed wonderfully with the ideas of ventilation. Where a few years ago there were a few furnaces made, there are now a hundred, and all have been improved to a point that late comers in the field must expect to exercise the greatest ingenuity in order to get a foothold under the strong competition that exists. When a general idea is secured there are many who can go ahead with it and improve it. There are few persons who could devise the hot air method of heating at the outset, but once given the idea, there are hundreds who can go ahead and improve the original idea. This is true of anything, says the Hardware Trade.

Mr. Wm. Lockman, a veteran builder of Hamilton, Ont., who is now in his 86th year, is at present engaged in the erection of a residence for himself, and is preparing with his own hands all the woodwork for the building.

The officers of the Bras d'Or Marble Co., Limited, for the current year, are: President, Rod. McDonald, Halifax; directors, Messrs. G. E. Franklyn, R. Uniacke, H. Saunders, S. Mosher, and G. Hattie, of the same city.

A preliminary meeting of the master plumbers of St. John, N. B., was recently held to consider a basis of organization for an association of plumbers throughout New Brunswick and Nova Scotia. A meeting for organization will be held in a few days.

A bill was recently introduced in the British Columbia Legislature, to prohibit the employment of other than British subjects on provincial or municipal works to be paid for out of taxation, and to establish eight hours as the legal working day. The Speaker ruled the bill out of order on the ground that the matter was one which belonged to the jurisdiction of the Dominion Parliament.

Application has been made for the incorporation of the National Sculpture Society, the object of which is to establish a school of sculpture in Montreal. The proposed capital is $50,000, divided into 500 shares. The petitioners for incorporation are:—Messrs. Henri Lemaire, notary; Arthur Fiset, notary; Pierre Catelli, manufacturer; Edouard Pambrun, gentleman, and Charles Auguste Rocher, advocate, all of Montreal.

Mr. H. Gillen, architect, Kingston, Ont., agreed with the proprietors of the hotel Quinte at Belleville, to do the necessary architectural work on their new building, which was to cost $25,000. The building actually cost $36,000, and Mr. Gillen in rendering his account increased the amount of his fees in proportion to the increased cost of the building, and upon payment of the account being refused, brought action in the courts to recover his charges. The Judge decided that the hotel company were entitled to pay the increased amount.

POPULAR IMPRESSIONS vs. FACT.

AVERAGE human nature has a strong affinity for that which partakes of the mysterious. The superstitious is bred in the bone of most men. They like to speculate on that of which they know little or nothing. This, at least, would seem to be a generous way of accounting for many of the absurd opinions given out regarding the recent great fires in Toronto. Experts have shown how far off were those wise ones, who would have connected the Simpson fire with that subtle force electricity. In a previous number of the ARCHITECT AND BUILDER, it was shown that those who talked of the Simpson building as fire-proof, and would berate all and sundry who had anything to do

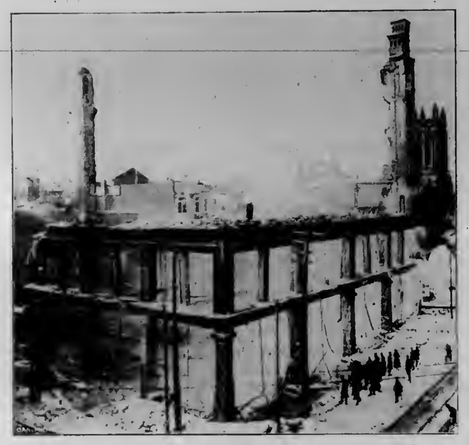

ILLUSTRATION SHOWING HOW PROTECTED IRON COLUMNS WITHSTOOD FIRE IN THE SIMPSON BUILDING, TORONTO.

with its construction, were simply talking of something they knew nothing about. Considerable notion seems, also, to have existed, and to some extent where better views ought to have prevailed, that had some other method been adopted in the placing of the large iron columns and beams that formed an important factor in the Simpson building, they would not have been so completely damaged by fire, as was manifest to everyone the morning after this unfortunate event.

The ARCHITECT AND BUILDER has taken some trouble to investigate this matter. Let us examine into the facts. It ought to be understood by this time that the Simpson building was not designed to be fire-proof. The internal columns and beams were of rolled steel and had to be of this material, as the spans were too long for wooden beams. The clear unobstructed space was a *sine qua non* necessitating as few columns as possible. In the case of buildings erected for office purposes, though of great height, and on the same plan, this condition does not apply to the same extent. But in large stores and warehouses great open space is a necessity. It was for this reason that the joists were of southern pine, the span and load being too great for the strength of the ordinary native pine. Objection has been taken to the use of southern pine in large buildings, because it is more inflammable than the white pine, but so far as the present case is concerned, with a fire of so great intensity, such a condition was neither here nor there, any more fire-proof substance must have succumbed. The plastering throughout the building was of acme cement, the columns being also plastered with it on metal lath. This protection would have successfully resisted an ordinary fire in the new building, but was powerless, of course, to resist the intense heat developed in the old adjoining buildings, which were directly connected with the new, without the interposition of any wall.

It has been said of the Simpson building that the steel columns, which extended from the ground line to the top of the second storey were inadequate to carry the weight of the building, and that the large masonry columns were partly used to give strength to the steel work.

The ARCHITECT AND BUILDER has made careful enquiry on this point, as it is one of importance, particularly from a structural point of view. Our information shows that the outer walls were carried from the third storey entirely on the steel columns, which extended from the ground lines to the top of the second storey. These columns were encased afterwards with cut stone, brick and terra-cotta. The protection of these columns and the beams which they carried was so thorough, that paper signs which had been pasted on them were intact when the brick work was taken down. The stone and terra-cotta of the two lower stories in no way supported the building, and were only a casing or ornamental and protective feature. All the columns and beams were calculated with the usual factor of safety and no settlement or structural defect of any kind, we have reason to believe, had shown itself up to the day of the fire, although the building had been rushed through in an unprecedentedly short time and under many adverse conditions.

Had it been intended to make the building fire-proof, the iron beams, which, as our illustration shows, became so terribly twisted, would have been encased in fire-proof material, such as porous terra-cotta. But this was not done. Profiting by the experience of the late fire, we are glad to learn, for the general safety of the city, that the new building that will be erected for Mr. Simpson, by the same architect, will almost certainly be made fire-proof.

We have heard comparisons made between the methods of construction adopted in the erection of such buildings as those of Simpson's and McKinnon's and some of the high buildings of New York and Chicago. It does not appear, in these larger cities where this plan of building is so much followed, that very much better methods of fire protection and construction are adopted than in Toronto, where the experience has not been nearly so great. The fact is in a composite building like either of those named, where wood, steel, and masonry work go into the structure, no better guarantee can be given in one place than another that a conflagration, when it gets headway, will not destroy it, providing, of course, proper fire equipment is possessed by the municipalities. The writer discussed this matter with a well-known local architect, who had, at one time practised in New York, and he cited the case of the destruction of a large warehouse there, built on somewhat similar lines to that of Mr. Simpson's, and where the result was just as disastrous.

Whether it is wise to encourage the erection of buildings, constructed on what is familiarly termed the skeleton plan, is a

ILLUSTRATION SHOWING THE EFFECT OF HEAT ON UNPROTECTED IRON GIRDERS IN THE SIMPSON BUILDING, TORONTO.

point on which architects and practical men will differ. Perhaps the greater safety lies in the adoption of a happy medium, where steel and iron will be mainly used, and yet, where, as we understand is the case in New York, masonry work is not discarded to nearly the same extent as in Chicago. There is just this about it, that where masonry work is employed, the openness and light aimed at, especially by owners of large stores, has to be sacrificed. And wisely or not, in this intensely practical age, utility more frequently predominates in settling these matters than any other influence.

Mr. Andrew Taylor, R. C. A., recently delivered a lecture before the Woman's Art Association at Montreal, on "The Importance of Form in Art."

ELECTRIC LIGHTING FOR LARGE BUILDINGS.

BY GEO. WHITE FRASER, E. E., TORONTO.

THERE have, until recently, been but two general methods employed for the electric lighting of large buildings. 1. The renting of the current from the electric company operating a central station; and 2. The installation in the building itself, of a private generating plant. There can be no rules laid down, of general application, pointing to the adoption of either method preferentially to the other; every case must be considered on its merits. Such consideration will reduce the question to its lowest terms, viz., a comparison of the costs of lighting by the rival methods. The variable quantities that will enter into this reduction as governing factors are: The price of current supplied from the central station per lamp hour, or per kilowatt hour on the one hand, and on the other, the cost of generating the current required in the building, using a private generating plant. This latter cost will be the total of such items as coal and water, etc., engineer's salary, little repairs, depreciation of plant and interest on capital expended in purchase of machinery, etc.

It is evident that local data will greatly influence the selection of method. For instance, a building full of dingy offices, and employing already an engineer and using quantities of steam, for heating, might very reasonably be expected to effect an economy in lighting by using a private engine or dynamo; while a church using a number of lights periodically, would not. These are, of course, extreme cases, illustrations merely of the general principle, but it is a great mistake to assume in all cases, that because there is a central station operating, it must be better and cheaper to rent current instead of generating it.

The object of this article is to introduce to the owners and designers of large buildings a modification of each of the two general methods described above, that have the merit of presenting very interesting features from an engineering point of view, and of promising well from that of the owner.

The first modification is the use of a gas engine instead of a steam engine, to run a dynamo in a private installation. This plan presents many very advantageous features. No boiler is required, with its coal dust, dirt, and chance of explosion. Less ground space is taken up. Gas engines are very largely used in Europe, and in the States for working dynamos, and many of them are absolutely guaranteed to use only 15 cubic feet of gas per horse power per hour. In connection with this, there is a very interesting and suggestive calculation easily made. Thus:—One thousand cubic feet of gas in Toronto costs the consumer $1.10 for lighting purposes, and 90c. for power and heating purposes. If burnt in a 5 foot burner, this thousand feet will give 3200 candle power hours. If consumed in a gas engine requiring 25 feet per horse power per hour, this 1,000 feet will give 40 horse power hours. These 40 H. P. h., if used to run a dynamo, assuming 75% electrical efficiency and 4 watt lamps, will give 5584 candle power hours. The Toronto Incandescent Light Co. sells current at the net rate of 6 cents per 160 candle power hours, barring special arrangements.

Reducing these prices down to their equivalents per 1,000 candle power hours, gives:

Gas in burner.....	costs,	34.375 cents	per 1,000 c. p. h.
Gas Engine and Dynamo	"	16.177 "	" " " "
Tor. Inc. Co.	"	37.500 "	" " " "

Now, one 16 candle power incandescent lamp burning for 62½ hours is equivalent to 1,000 c. p. h., so it can be seen how, in a large building requiring extensive illumination, it may very easily be actually less expensive to run a private dynamo, operated by a gas engine, than to rent either gas or current. So far, there is a difference, in favor of the gas engine, of over 100 per cent., but no account has yet been taken of two considerable items, salary of attendant, and interest and depreciation. These will of course greatly increase the cost as calculated above, but to what extent depends entirely on the size of the installation; there seems to be, however, a considerable margin to come and go on.

The second modification is the use of a storage battery located in the building, and kept constantly charged by wire from the central station. I am aware that the advantages of this plan are open to criticism, and would have to be the result of special arrangements with the central station. I am also aware that "Central Station Management" as understood in most Canadian stations, except the really large ones, is not the science that it has become in the States and Europe, and that as a fact, so little attention has been given to its study, that managers do actually not know those conditions of operation which are productive of best financial results to themselves. At the same time I am convinced that a little persevering effort on the part of interested persons would bring about a state of affairs favorable to the economical operation of the modification I have just suggested.

The position may be briefly and clearly described thus:—The best and most paying load for a central station is a *constant* one, one that doesn't jump from 0 at 5 o'clock p.m. to 500 H. P. at 8 p. m., but that remains fairly steady all the time. This is just the very kind of load that a storage battery gives, and moreover, it presents another very attractive feature to the central station as follows: A building is wired for say 500 lights; it will use these 500 lights all at the same time two or three times a year, but the machinery in the central station has got to have this 500 light capacity consuming interest and suffering depreciation all the year round, although it earns money only three or four times a year. A storage battery, however, that can be charged at the rate of 20 amperes continuously, will give out when required the whole current for the 500 lights, and keep them going for four or five hours. Thus the central station will only have to provide generating machinery sufficient for 20 amperes, which will be earning money all the time, instead of sufficient for 500 amperes which will be idle most of the time. Consequently it is to the obvious interest of the central station to encourage the use of the battery, and in order to do so it will lower price of current. A very well known authority on electric matters, has stated that it would pay central stations to sell current (for use with storage battery) at 4 cents per kilowatt hour in order to get the constant load that is so advantageous. This figure is equivalent to 16 cents per 1000 candle power hours, and to this must again be added interest of and depreciation on accumulators. Here again particular conditions will affect the total per 1000 c. p. h., but as in the former modification a considerable margin is left. I have no doubt, that central stations would see the advantage of lowering their rates on such loads, if the case were properly presented, and advantage to both parties would result.

There being no particular installation to study, it is impossible to be other than general in this article; it was intended merely to point out to parties having large buildings to light, or to supply elevators for, that there are several ways of doing it, each of which is best only under certain favorable conditions, while under different conditions it should give place to some more efficient method, the actually best method being determined only after due consideration of the peculiar conditions.

BRIBES TO ARCHITECTS.

THE Southern Chapter of Architects, at its last convention, adopted the following resolutions:—

WHEREAS, The architect is in effect the trustee or agent of his client, and in that capacity shall endeavor to serve the client to the best of his ability, and to secure for him (the client) the full value received of the work under his charge; and

WHEREAS, It has been suggested to this convention that some material men have been tendering to architects commissions to secure the sale of their materials, the acceptance of which is contrary to our code of professional ethics; therefore, be it

Resolved, That we, the Southern Chapter of Architects, condemn such methods as dishonorable and to be discouraged by all legal and honorable means.

We further consider all material men, and others, resorting to such methods, as unworthy to hold business relations with members of this Chapter.

Resolved, That after the board of directors shall have received sufficient proof of such practices, or attempts, it shall notify the secretary, giving him the names of the parties transgressing, which names the secretary shall thereupon transmit to each member of this Chapter. Be it further

Resolved, That these resolutions be published, printed and distributed for the general information of material men, architects and the public at large.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

MONTREAL MASTER PLUMBERS' ASSOCIATION.

SIX years ago a movement was started by leading master plumbers of Montreal, such as Messrs. John Date, F. Hortan, Jos. Lamarche, J. W. Hughes, W. A. Stephenson, J. C. Jacotel and A. Champagne, to form an Association of their own in connection with the Montreal Contractors' Association and as a section of the same, but unfortunately the efforts of these gentlemen ended fruitless with a banquet held two years after at the Richelieu Hotel. They and others having the welfare of their profession at heart were, however, not discouraged by their past experience, and new efforts were again made last summer to successfully carry out the scheme. A general meeting of all the master plumbers of the city and suburbs was consequently called last July to discuss the advisability of organizing the proposed Association, which was responded to enthusiastically by nearly all the plumbers of the city and suburbs. A committee was entrusted with the task of preparing a constitution and by-laws, and at a general meeting of the craft held for the purpose on Aug. 3rd these were discussed and adopted, and at the last session of the Provincial Legislature the Association secured its charter through Mr. C. Beausoleil, M.P.P.

MR. J. LAMARCHE.
President Montreal Master Plumbers' Association.

Since then, although a very short time has elapsed, the Association has been very active, and has more than once proved its utility. The new plumbing by-law of the city, passed last June, has been studied, and although admitted to be a great improvement on the previous state of affairs, suggestions were drawn up and sent to the Health Committee of the City Government, which they have now under consideration. Not only has this Association been established with the view of an interchange of professional knowledge and ideas amongst its members, which would be beneficial to them alone, but its field extends far beyond that, its object being also to instruct the general public in matters pertaining to hygiene and plumbing, by means of popular lectures given free at regular intervals by prominent hygienists and physicians, of which two have been recently given—the first by Dr. Lapthorn Smith, and the other by Dr. E. P. Lachapelle—which were a marked success, both in respect to attendance and instructiveness.

The Association has not forgotten either the important matter of giving proper instruction to apprentices. As a step toward this, the Department of Plumbing at the School of Art and Manufactures, now one of the most important at the school, has been placed under its control, and a committee has been appointed to look after its welfare and regulate its instruction. A reorganization of the Department is contemplated at the next session. The Association meets every second and fourth Thursday of each month at St. Joseph's Hall, corner St. Catherine and St. Elizabeth streets. A standard price list is now under consideration for adoption by the manufacturers of and dealers in plumbing materials, so as to put a stop to selling to private individuals at the same prices as to the trade, a practice which has been indulged in for some time to the injury of the trade.

The Association opened a branch on the 8th instant in Quebec, and propose also to establish similar branches in all the principal cities of the Province, and at St. John, N.B. Negotiations are now pending to amalgamate this Association with the Toronto Master Plumbers' Association, so as to make it a Dominion Association, and before the close of another twelve-month it is said that it will form part of the National Master Plumbers' Association of the United States.

The Executive Committee of the Association for the ensuing year is composed of Messrs. J. Lamarche, President, whose portrait accompanies this article; John Date, 1st Vice-President; A. Champagne, 2nd Vice-President; Henry Padden, 3rd Vice-President; W. M. Briggs, Secretary; J. W. Hughes, English Corresponding Secretary; Joseph Gibeau, French Corresponding Secretary; J. C. Jacotel, Financial Secretary; W. A. Stephenson, Treasurer.

On the refusal of the trustees of the French Baptist Church, corner St. Catharine & Cadieux streets, to take down the building which was recently condemned, on the ground of its being built contrary to the regulations of the building by-laws, and being a menace to the safety of pedestrians, the Building Inspector commenced to tear down the building on the 9th instant. All the exterior of the building was about completed, and the roof was being put on. It is understood that the building has been taken out of the hands of the architect, Mr. G. Mann, and given to another city architect to rebuild.

WATERPROOFING BRICKS.

AT a recent meeting of the Australian Association for the Advancement of Science, Professor Liversidge read a paper on the "Waterproofing of Bricks and Sandstones with Oils." These experiments were made with the view of ascertaining the length of time that bricks and sandstone are rendered waterproof or protected by oiling. The oils used were the three commonest and most readily obtainable for such purposes, viz., linseed oil, boiled linseed and the crude mineral oil known as "blue oil," used for preserving timber. The weatherings were made upon a flat portion of the laboratory roof exposed to the sun and weather. Good sound machine made bricks were experimented on. The amount of oil and water taken up by the sandstone was very much less than that absorbed by the bricks, although the area of the sandstone cubes was much greater than that exposed by the bricks. Equal amounts of the raw and boiled oils were absorbed; the blue oil, however was taken up in much greater quantity by both bricks and sandstone, but by the end of twelve months the whole of the 13½ ounces of blue oil had apparently evaporated away, and the brick had returned to its original weight, but those treated with raw and boiled oils remained unchanged. After the second oiling in November, 1890, and exposure for nearly four years and two months, they had practically retained all their oil, inasmuch as they had not lost weight and were practically impervious to water. It was noticeable that the sandstone cubes treated with raw and boiled oils returned to their original weights, but do not appear to have lost the beneficial effects of the oils, being practically impervious to water.

The March number of the Indianapolis Clayworker contains illustrations of the Beamsville Brick Company's works, and of specimens of the material produced therefrom.

Reports from Windsor, N. S., state that the plaster business for which that locality is celebrated, will be developed to an unusual extent during the present year. One company alone will, it is said, ship about 100,000 tons to New York.

The Master Plumbers of the city of Quebec held a meeting on the 19th of March, to consider steps for the organization of a Plumbers' Association for that city. A committee was appointed to appoint officers and a second meeting to complete organization will be held shortly. The Association will endeavor to prohibit journeymen and apprentices from competing with master plumbers, and supply houses from selling to any but the legitimate trade. The City Council of Quebec are taking steps to improve the sanitary condition of the city.

STUDENTS' DEPARTMENT.

AN AUSTRALIAN EXAMINATION PAPER.

THE following papers were set for the last associateship examination of the Royal Victorian Institute of Architects:—

STYLES OF ARCHITECTURE.

1. Name the five orders of Classical Architecture, and give their principal proportions and leading features, and illustrate the descriptions with sketches.

2. Explain and illustrate by sketches the meaning of the following terms: Billet, cortile, flèche, loggia, carona, telamones, systile, sgraffito.

3. Give briefly the leading characteristics as to plan, construction and ornament of the Greek, Roman, Romanesque and Gothic periods, and give rough sketches.

4. Write a brief description of two of the following buildings, giving the style and dates and names of their architects: Church of St. Vitale at Ravenna, Cathedral of Pisa, Cathedral at Florence, Library of St. Mark's at Venice.

5. Write a short description of one only of the following buildings: Salisbury Cathedral, Henry VII. Chapel, Westminster.

6. Sketch the differences in plan and section between the Basilican form of churches and the Gothic cathedrals of the late twelfth century.

7. Give a short account of some building designed by Palladio, Inigo Jones and Philibert De Lorme.

8. Name a typical Romanesque church in Germany or France, its date and particular features.

9. Name some representative French cathedral and describe it.

10. As to the accompanying ten photographs, give in each case (*a*) the style, (*b*) the county or locality, (*c*) the order, period or century, (*d*) explain upon what details of feeling you base your opinion, (*e*) if you recognize the building, give what particulars you can in addition.

MOULDINGS, FEATURES AND ORNAMENT.

1. Drawn to a scale of ½in. to 1ft., a Greek Ionic column showing cap and base, lower diameter to be 3ft.

2. Drawn to a scale of 1½in. to 1ft., the entablature carried by column above, and write against the various portions thereof the name each bears.

3. Describe the use of the human figure as a decorative feature in Greek buildings, and name the parts of a building in which such decoration was usually put.

4. What are the leading characteristics of Romanesque mouldings, and from what sources are they derived? Illustrate with sketches to large scale.

5. Describe and illustrate by sketches to large scale the following terms: Gargoyle, flèche, battlement, dormer, finial, sedilia, machicolation, peristyle, crochet and ballflower.

6. A doorway is to be formed in a stone wall 3ft. thick, the opening to be 10ft. wide, drawn to scale of 1in. to 1ft., the arch-mould and plan of jamb (*a*) in the thirteenth-century Gothic style, (*b*) in the fifteenth-century Gothic style.

7. Sketch a Gothic buttress, also a flying buttress, and describe the origin and use of the latter. State the period which your sketches represent.

SHORING AND SANITARY SCIENCE.

1. It is proposed to convert the front of the warehouse, shown in drawings A, into a shop, and to put a cellar extending back 24ft. and the full width of the building and 10ft. high from floor to ceiling. Describe in order each operation necessary to carry out this work, and illustrate by pencil sketches to scale.

2. When rain-water from the roofs has to be conveyed to the sewers, what precautions must be taken to prevent egress of drain air from the down-pipes in very dry weather?

3. As to water-closets. Describe and sketch some of the best types, and state their relative advantages and disadvantages.

4. How are automatic flushes produced? Describe and sketch some of the apparatus, and state under what circumstances their employment is necessary or advisable.

5. What is meant by the term "seal"? What should be the amount? How is it liable to be diminished? How can the latter be avoided? Give rough sketches.

6. Fig. 6 shows a plan of a building with stables at rear, and the w.c's., sinks, bath, &c., are marked. Sketch on the plan the various drains, waste-traps, &c., you would adopt, and describe and sketch the various fittings, connections, &c.

7. As to underground tanks, what special precautions must be taken in their construction and in the arrangements of supplies and overflows to avoid pollution of the water.

USEFUL HINTS.

It takes 813½ cubic feet of air to weigh as much as one cubic foot of water. If 813½ cubic feet were compressed into the space of one cubic foot, its weight would be about the same as an equal volume of water.

Radiant heat passes through moderate thicknesses of air and gas without suffering an appreciable loss or heating them. When a polished surface receives a ray of heat, it absorbs a portion of it and reflects the rest. The quantity of heat absorbed by the body from its surface is the measure of its reflecting power.

Admirable results may be obtained in interior decoration by confining the colors to creamy browns and relieving the color with gold. For instance:—Ceiling, white with a touch of cream; paper, rich cream ground and open floral design with gold; as bold a frieze as the height of the room permits; and woodwork also in creams, with the styles and rails, of course, much darker than the panels. A room decorated in this way presents a warm and charming effect that would be admired by nineteen out of twenty people of good taste.

In estimating temperatures under conditions where the thermometer is not suitable, such as in the uptake, of breeching, of a boiler, says the Master Steam Fitter, the following list of melting points of metals may be of assistance: Plumber's solder, two parts lead, one part tin, melts at 440 degrees; tin melts at 428 degrees; lead melts at 612 degrees; zinc at 793 degrees. It will be noticed that the addition of tin has a peculiar effect in reducing the melting point of the alloy below the temperature at which either of the component metals melt. With fine solder, which is one part lead and one part tin, melts at 370 degrees.

The manner in which mosaics are now made for decorative purposes is quite different from the elaborate system used by the ancients, which consisted in fixing the tesserae one by one on the cement previously applied on the wall. The modern method of the Venetian school consists in executing the mosaics in the workshop, by having the tesserae fixed with common paste on the section of the cartoon assigned to each workman. When all the parts of the mosaic are complete, they are put together on the floor or on a special wooden frame. The mosaic, which is then a perfect representation of the original cartoon, is again divided into sections on the reverse side, marked with a progressive number and carefully packed to be sent off to the place for which it is intended. The surface of the wall where the mosaic is to be fixed is then covered with cement, into which the sections of the mosaic are uniformly pressed, according to their numbers and the key-plan supplied to the fixers. When the cement has hardened, the paper on which the tesserae have been pasted is gently taken off, and the faithful copy of the original cartoon is again exhibited on the right side.

A GLASS ERA.

GLASS is a material whose astonishing possibilities we are only beginning to realize. Great progress in its manufacture has been made in the last ten or twelve years, blowing by compressed air having greatly increased the quantity and variety of the work that can be produced, while improved methods of moulding have made possible castings of large size. Large glass pipe, unaffected by the soil and having the strength of cast iron, is now turned out in considerable quantities. The material can also be made into plain and ornamental bricks, chimneys, furniture, and even tapestries and complete houses. M. Henrivaux, an enthusiastic French manufacturer, proposes to exhibit a glass house of novel design at the Paris Exposition of 1900. An iron skeleton will be erected, on which will be placed slabs of glass in such a manner as to form a double wall, in the interior of which hot air will be circulated in winter, and compressed air—which will cool the walls—in summer.

BOOK CASE AND WRITING TABLE FOR CUYLER A. HALLAND, —DESIGN BY R. MACKAY FRIPP, F.R.I.B.A., VANCOUVER, B. C.

RIEVAULX ABBEY, YORKSHIRE.

THE site selected for the Abbey was on the sloping bank of the Rie. The Valley of the Rie is so tortuous that, looking from the Abbey, it seems to stand in a magnificent amphitheatre, surrounded on all sides by hills clothed with trees rising to the level of the moors above. From its situation it obtains the name of "Rievale" or "Rivaulx," and is called in the neighborhood "Rieval" and "Rivers." It was founded by Sir Walter d'Espec, who endowed his foundation with the manor of Hamelac, with wood and pannages for their hogs in his forest and four carncates of land (a carncate being as much as one team could plough in a year). Its first Abbot was William, a monk of Clairvaux (1131–1146),—"a man of great virtue and excellent memory"—the last, Richard or Rowland Blyton, who, with 23 monks, signed the surrender. The history of Rievaulx is meagre and uneventful, sheltered as it is in its secluded valley—the highroad to and from nowhere. The brethren appear to have commenced building a small stone church in the prevalent Norman style immediately after their settlement, of which nothing remains except the lower portion of the transept, which was incorporated with the new church built by Archbishop Abred, in the pointed Gothic which was then becoming fashionable with the Cistercian order. The choir, although roofless, is in a tolerable state of preservation, although portions of the outer walls of the aisles are gone. The aisles were separated from the centre by ranges of clustered columns, with bandings instead of capitals, from which spring richly moulded pointed arches. Above the triforium the centre spandril, ornamented with quatre foils in sunk circles. At the east end are six lancet lights—three and three—the upper tier with clustered shafts and lozenge mouldings, and flanking these at the end of the aisles are two smaller lights, all richly moulded. The turret staircases to the triforium were placed at the angles, but only one now remains. The clerestory windows are also lancet—fourteen on each side—in pairs under an arch outside. Each pair is flanked by a smaller blank lancet. The refectory is a noble apartment 100 feet by 30 feet, situated on the west side of the Quad.

The ruins were at one time much overgrown with ivy, which has been removed. At the dissolutinn the commissioners caused the lead to be stripped from the roofs of the church, the Abbot's house and other buildings, nearly all of which remain sufficiently to trace out the whole plan, and it is remarkable that the mouldings are as sharp and clear to-day as when they left the builder's hands.

Many abbeys have sprung from Rievaulx—notably Melrose, Revesly and Rufford—and its influence spread to York and Fountain, many of them passing under the Cistercian rule. The Abbey of Byland is within a few miles, and the whole district is rich in antiquities. Rievaulx is owned by the Duncombe family, whose seat is at Hembley, the nearest town.

A POMPEIIAN BATHROOM.

A VERY interesting discovery recently made near the old site of Pompeii is described in the European journals. A large building was unearthed on the property of a Signor de Prosco, containing several rooms, among them three bathrooms, furnished with large sculptured marble basins, heating apparatus, lead plumbing work, with bronze faucets, and tiled floors and walls. The three rooms correspond in their arrangements with the usual hot, tepid and cold baths usually found in the old dwellings of the wealthy classes. This is, however, said to be the most complete, richest and best bathing installation so far found. It has been so well preserved on account of the roof not having caved in during the great eruption of Vesuvius which buried the city of Pompeii in the year 79. Most of the houses were entirely destroyed at that time, only a few vaulted structures resisting the immense pressure of the lava and ashes. This roof is nearly 45 feet in length.

THE APPLICATION OF COLOUR TO ARCHITECTURE.

By G. F. STALKER.

FOR a very long period the idea prevailed among architects, and the public, generally, that the application of colour to buildings, in any way whatever, was a sign of effeminacy or pedantry, or a lack of taste. It was considered that anything which interfered with the tameness of tone in the material of which a building was constructed, interfered with, if it did not altogether destroy, the purity of the style in which it was designed. Whether this was the result of a most unhappy misconception, or a want of knowledge of the laws of colour and how to apply them, it is difficult to say. Probably it was a little of both. But whatever the cause may have been, the result was, that for many generations, architecture and colour were divorced. Precedent, that fickle and uncertain mistress, was dragged from Egypt, Greece and Rome to prove that colour was shunned by the ancient architects in their work, and that they depended entirely upon the proportion of their buildings, and the elegance of their detail and ornament for the matchless beauty which they possessed.

Still the eyes of men looked for something more than form, (however perfect) and light and shade, (however well disposed), and some restless spirits examined and analyzed the ancient precedents until they discovered and established beyond a doubt, that colour was applied, and that extensively, to architecture, by all the nations of antiquity. The anti colourists had omitted to reckon with Father Time, who, though he had not altogether destroyed the buildings of the ancients, had almost wholly obliterated the colour with which they had adorned them. Further investigation has shown that the combination of form and colour was well understood and practiced by every ancient people who have made their mark upon the world by the excellence of their architecture. And this is the more remarkable particularly in regard to the three nations mentioned, when we consider the care which they must have bestowed upon every detail of their structures. For we cannot but be impressed with their exquisite beauty if we see them only in photograph or in drawings in black and white. Add to this the colouring which architects of such perfect taste would apply to their buildings, and if from the meagre basis which time has left us, we can re-animate them, we should have before us the most perfect examples of architecture.

Following the ancient and natural lines, the Byzantian and Rennaisance architects gave great prominence to color in their work. In many instances (particularly in Italy) they sacrificed architecture to such an extent that it became a sort of framework for mural painting and decration. But, on the whole, their work was done in such good taste, that the defects in architectural detail were atoned for in the beauty of the colortng, and so, philosophically, it has been allowed to pass. Such an apology, however, would not hold good at the present day. There were thousands of excuses which could be given for the delinquencies of that time, which cannot, in fairness, be put forward now. We accept what they did, in good faith, based on the knowledge they possessed. Future ages will expect the same of us. We have all their work before us as examples to follow or shun, and we shall act foolishly if we do not profit by them.

In mediæval times the architects followed in the same lines as their predecessors. It is true, (all honor to them for it) they returned to the ancient practice of giving prominence to form. But they did not neglect the application of colour. They applied it to their columns and roofs, to their wall spaces and to their windows. Crude in many cases, no doubt, broken necked and out of joint are many of their figures. But the effort was there, and the aspiration which in such case covers a multitude of sins.

It is since the middle ages that the unfortunate divorce of colour from architecture has taken place. Various attempts have been made of late years to effect a reconciliation. In view of the fact that they were formerly wedded, and that they have never separated of their own desire, and that there is still, as there always has been, a strong affinity between them, it is surely the duty of all architects to bring them together again to live in harmony with each other. There are many reasons why this should be done in Canada, and many opportunities for doing it. One reason may be sufficient. In the sunny countries of Italy and Greece they enhanced the beauty of their otherwise beautiful

buildings by the application of colour to them. The sun shines on these countries from January to December, giving them changes of natural raiment only varied in beauty from one season to another. One would imagine that buildings devoid of colour would be suitable in such places. But the luxurient colouring of nature has created in them a demand for colour everywhere. Then the supply is provided for the demand. The clays and marbles of Italy are ready to hand, and by skillful application, their structures lose all their strength or purpose but gain much in their appearance and grace.

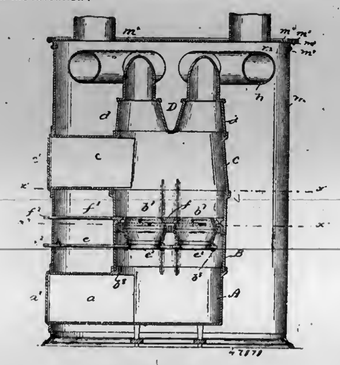
We cannot speak of our country as Sunny Canada, but we can hazard an opinion that there are few countries in the world of such varied colouring as our own. It is true we have not continual summer. But when summer is here it is brilliant; and our fall is so rich in colour, that it seems as if nature would provide us then with beauty enough to last us through our long, cold and colourless winter.

If the people in the sunny southern climes find pleasure in colouring their buildings, is it likely that the people of the frozen north will take less pleasure in the relief which colour will afford them? This is not likely. But the people will never take the initiative. It is for architects to do that. It is true that something has been done in this direction of late years, but it has been in such a hesitating, imbecile way that it is scarcely noticeable

In applying colour to our buildings, however, it is necessary to say that, externally at least, the colony should be constructive. And, so far as this is concerned, we are happily circumstanced in Canada. We have within our Dominion almost every variety of granite, marble, stone and clay to provide us with the means of applying colour to our buildings in the most artistic and, at the same time, constructive manner. It may be, however, that our architects have not given this matter that amount of study which the subject merits. Appearances have that look about them. If, however, architects would consider that colour is one of the essential details of their profession a very few years would make a wondrous change in the tone and character of our buildings.

RECENT CANADIAN PATENTS.

No 47,878, for a heating apparatus, to Henry Ransom Luther, Cambridge, Mass. The accompanying illustration and statement of claim will serve to explain the invention :—

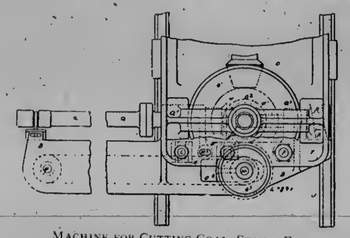


HEATING APPARATUS.

In a heating apparatus, a fire pot, an upper grate surface supported therein, means to shake said upper grate surface in sections, a series of independent pockets depending from said upper grate surface, a pocket support, a series of lower grate surfaces in the said pockets, and a common axis connecting said lower grate surfaces in series, whereby they may be rocked. In a grate of the class described, the combination with upper and lower grate surfaces, of pockets depending from the former and inclosing the latter, the upwardly and outwardly inclined, baffle surfaces on the sides of the said pockets to deflect the air or gases rising between the same away from the side walls of the pockets at the tops of the latter.

No. 47,891, for a machine for cutting coal, stone, etc., to Thomas Heppell, Leafield House, Chesterle street, William Patterson and John George Patterson, of Hardwicke Terrace, Gateshead, Durham, Eng. The following illustration and statement of claim will serve to explain the invention :—

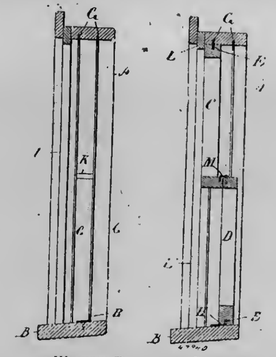
In a machine for cutting coal, stone and similar hard substances, the combination with a backstay B, pivoted to a suitable trolley, the means for locking the said backstay in its working position, of the cutter-bar A, mounted in bearings A1 and A2, on the inner end of the backstay, and a sliding bearing K, at the outer end of the backstay, cams R, R1, on the inner end of the said cutter-bar, a fixed pin S1, on the said backstay engaging the



MACHINE FOR CUTTING COAL, STONE, ETC.

said cams, a convey or chain or debris-removing apparatus carried on wheels journalled in the said backstay at M, M, and means for revolving the said cutter-bar and wheels carrying the said debris-removing apparatus.

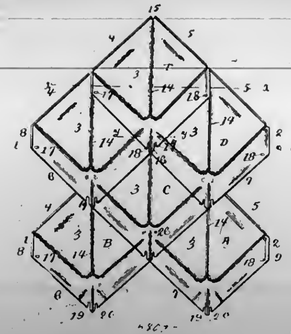
No. 47,940, for a window frame and sash, to Charles Day Morson, Park Hill, Ont. The accompanying illustration and statement of claim will serve to explain the invention :—



WINDOW FRAME AND SASH.

1st. The combination with the window frame, having parallel tongues G, at the sides, and a tongue at the top and sill, of the upper and lower sliding sashes C, D, having grooves at the side edges and at the top and bottom, and receiving said tongues. 2nd. The combination of the upper and lower sliding sashes, the meeting rail of the upper sash provided with a metal strip or tongue M, fitted into a groove in the meeting-rail of the lower sash. 3rd. The caskets K, secured to the window frame intervening the parallel tongues E, and opposite to the ends of the meeting rails of the sashes.

No. 48,037, for metallic roofing tile, to Ephraim Benj. Repp. Washington, Col. The accompanying illustration and statement of claim serve to explain the invention :—



METALLIC ROOFING TILE.

An approximately rectangular roofing tile having cut away sides 1 and 2, and provided with a rib 9, at one side 2, and an upward projecting flange 8, at its side 1, having holes 17 and 18 at the lower ends of the cut-away sides 1 and 2, and provided with points 19 and 20, at its central lower end, having a nail-hole 24, at the apex of a rib running along one side of the tile, and a raised portion 26, to accommodate the head of nail passed through a similarly situated nail-hole, of an under tile, having ribs 10 and 11, and flanges on the upper sides 4 and 5, said ribs and flanges meeting each other at their outer extremities.

METHODS OF RAPID CONSTRUCTION.

In the Engineering Magazine for February there is an article by Mr. Francis H. Kimball, who, with Mr. G. K. Thompson, designed and superintended the construction of the Manhattan Life Insurance Building—one of the loftiest of the new American class of structures, or sky-scrapers—descriptive of the mode employed in completing it within a brief time. Mr. Kimball writes :—

The temptation to excel some other record in the quick-building line, together with a desire for quick returns from rentals, losing but one season, is more than the investor can withstand. The architect has no choice in the matter ; he must accept the inevitable, and bring to bear all his skill to accomplish the end desired in the best and most workmanlike manner.

It is not difficult, at the close of one of these quick-building operations, to trace the reasons which led to so successful a termination.

The most recent example in point of the actual time consumed in erection and in finishing the great bulk of the building —which has not been equalled up to the present time, pound for pound of iron and brick for brick of masonry—is the Manhattan Life Insurance Building, with which the writer is identified.

No comparison can be made between New York and Chicago records, as our building laws are more rigid, in that they exact a greater degree of stability in the structural features.

In the case of the Manhattan Life Building, the time consumed in its erection may be divided into two parts, as follows : —Foundations ready for superstructure, five and two-thirds months ; superstructure, eight months.. The roof or eighteenth tier of beams was reached in exactly three months from the time when the foundations were ready, on which to set the first piece of steel composing the bolsters that support the cantilever system.

The time spent in preparing the foundations may seem to those unfamiliar with this work scarcely consistent with the progress afterwards made, but the architects found that, in view of the unsatisfactory nature of the ground composed largely of quicksand, the usual methods employed, such as piling of masonry, were inadequate for the purpose of a foundation to sustain the great concentrated loads, and they thereupon decided to reach bed-rock, 57 feet below Broadway, by some unprecedented means. They finally concluded to introduce the pneumatic process used in sinking bridge piers to rock.

Sinking the piers to bed-rock rendered the building independent of any outside operations, either building foundations or tunnels. The fact that they were the pioneers in this undertaking, so far as the application of this principle to building work is concerned, led to much carefulness on the part of the engineers, Messrs. Sooysmith & Co., in respect to the probable effect on the foundations of adjacent buildings, and that there might be no disturbance of such foundations, by reason of going so far below them, no attempt was made to force work to the degree attained in bridge-work where operations are carried on in an open country.

The magnitude of the work may be better understood by reducing it to cubic yards of masonry. This substructure, which starts on bed-rock and continues up to the level of the cellar floor, consists of fifteen piers, varying in size from 9 feet in diameter to 21 feet 6 inches by 25 feet square. The caissons made of steel corresponded in size to the piers they sustain, and were 11 feet in height. These caissons were filled with concrete, and contained altogether 1,260 cubic yards. The number of bricks used in the piers amounted to 1,500,000.

From this it may be seen that a good-sized building was sunk out of sight before any part of the superstructure could be begun.

The fact that a new method, with more or less experimental work attending its adoption, had to be devised, and the really large mass of masonry forming the piers, are sufficient excuses for the length of time consumed in this feature of the building. It was a work which in olden times might have taken twelve months. Even the progress attained was due to the fact that three relays, or gangs, of men were employed in sinking the caissons, thus giving the work the benefit of the full twenty-four hours in one day for the entire period of five and two-thirds months, except in the case of the masons, who worked only regular hours.

Suffice it to say that in three months about 5,800 tons of steel were raised into position. This was not accomplished, however, without night work. When the foundation work was prolonged to September 1, the prospect of completing the building on May 1 was not promising. A council was held—attended by the building committee, architects and builders—the purpose of which was to incite the builders to greater activity and also to settle upon a plan for beginning and continuing night work until the roof was reached.

This meeting resulted in the institution of day and night gangs of men for the erection of the steel frame ; and by reason of the time which, in consequence of the delay in the foundations, the contractors for this branch of work obtained for the making of the wrought material and the delivering of the same within a short haul of the building, coupled with the fact that great care was taken at the rolling mills in laying out the various members to templates, so that when they were assembled at the building no fitting was required, the work of erection went on without interruption from the beginning to the end. Recalling the incidents of these three months' work, and the system employed to produce the quickest results, it seems that no mistakes were made and that every moment was counted.

To better illustrate the magnitude of the skeleton, I may say that there were girders weighing 40 tons, many columns of 10 and 12 tons each, and cantilevers of 80 tons (in four sections of 20 tons each), the length being 67 feet.

All of these heavy members required special means of transportation ; the heaviest girder had to be rolled from the dock to the building by night, the task requiring three nights. It took just twenty minutes to raise it from the street to its position on the second floor.

On account of the great risks where material must be raised 300 feet in the air, and the haste with which the work must be done, the setters of iron and stonework should be picked men with certain qualities, the most prominent of which must be good judgment and steady nerves. It is rarely that serious accidents and even deaths are not recorded against buildings of even less magnitude than the Manhattan Life Building, but, strange to say, in this case there was no loss of life, and but few accidents worth mentioning. The work was greatly facilitated by the use of a travelling frame, with a derrick at each angle, by which material could be easily disposed of as it was raised from the street and placed in its proper position.

It was considered advisable to begin the brick masonry when four storeys of the steel frame had been set in position. This enabled the frame-setters to keep in advance of the other trades. As far as possible this plan was pursued throughout, but inasmuch as bad weather has no effect on iron and steel, while with masonry the contrary is the case, at times it was necessary to lay off the masons while the others pursued their work. When high winds prevailed all work had to cease. But with good weather, when all could work advantageously, the masons could hardly hold their own.

There seemed to be a friendly rivalry between the two trades as to which should outstrip the other, and the greater the exertion the brighter was the prospect of closing in the building before cold weather set in.

Rough piping both for plumbing and steam began when the masons had reached the fourth storey, and continued without interruption until all the lines, vertical and horizontal, with all their branches, were in position. In the meantime the masons had begun setting the fireproof blocks forming the partitions, and as far as practicable this was carried along with the advancement of the outside walls.

When the partitions of a storey had been set, the electrician ran his wires, enclosed in conduits, to the various fixture outlets. One can hardly realize now that this "roughing," as it is called by the workmen, is concealed from view—that more than five and a half miles of gas, water, waste and vent-pipes, five miles of steam pipes and thirty-five miles of electric wires were required to perfect the respective systems. The facing of the front on Broadway contains about 30,000 cubic feet of stone, which was cut and set in position in eighty days.

It was not at first the idea to undertake to finish more than ten storeys by the first day of May, as the plastering could not

be commenced until the winter was well advanced, and the outlook for enclosing the roof seemed distant and discouraging. When the twelfth storey was reached a temporary roof was deemed necessary for the protection from rain and snow of all the storeys below ; and such roof was constructed, and was of great help in removing all fear of damage to the finer grades of interior fittings.

Immediately thereafter plastering was begun, temporary heat was supplied, windows enclosed, and a general advancement made towards the completion of the storeys below. There was no cessation, however, in building above this temporary roof. Fortunately the weather was propitious, causing but little delay. The building was permanently enclosed by the time severe weather set in. Then all the forces that could be brought to bear were employed in the supreme effort of getting the entire building in such condition that tenants could occupy on the first of May any rooms that they might choose. It was successful. It proved a good investment for the company, as the greater proportion of the offices rented were above the sixth storey.

To follow all the different trades and describe the various methods employed to force the work almost beyond the limit of human endurance would be an interesting story. Suffice it to say that to the layman there can be no realization of the vastness of the undertaking.

Take the laying-out of the engineer's department—the boiler and engine, the electric and elevator plants, the plumbing and heating systems contained in a building of this magnitude, the decorative treatment of the interior, employing the carpenter and cabinet-maker, plasterer, marble-worker and metal-worker (on stairs and elevator fronts), the mosaic and tile flooring, gas and electric fixtures for lighting, to say nothing of a more or less ornamental exterior—and it seems hardly less than a miracle that all these different interests, all large because the building is large, could have worked harmoniously together, and achieved such satisfactory results in the period of eight months.

It might be asked, have manufacturers of building material kept up with the rapid advance in methods of handling, producing articles that will set more quickly, and reducing to the minimum the danger of destruction, such as that from dampness proceeding from brick, plastering and concreting ?

If the "drying out" of a building could be reduced to a few weeks instead of months, the length of time required for its erection would not be so much a matter of uncertainty. Some thought has been given to the mixing and manufacture of plaster, the application of which is made more simple than formerly by certain quick-setting qualities which make it practicable to put on the wood trimming within a few days after a room is white-coated.

There is yet room for improvement in the direction of freeing the process of plastering from dampness, and rendering it less objectionable from the standpoint of cleanliness to those who must follow the plasterers. But there is one feature of the mason's work to which much attention has been paid during the past ten years, but seemingly not in the right direction ; for the difficulty remains although the material is harder. I refer to fireproof blocking used for partitions and flat arches between beams. The blocks designed for partitions are not of uniform size ; therefore the surface of one side of the partition becomes very irregular, as the mason lays up one side to a line. The plasterer must even up with plaster, the thickness of which varies anywhere from half an inch to 1½ inch. It cannot be expected that the shrinkage of plaster will be uniform, to say nothing of the danger of freezing when the work is done in the winter months. Fireproofing of floors between beams consists usually of flat arches formed of terra-cotta blocks made hollow to secure lightness. These blocks do not make up a thickness equal to the depth of the beam, where the beam is more than 8 inches. They vary in depth according to the span between beams ; and where the beam is more than 8 inches there is a space above the arch to be filled, in order to meet the material of which the finished floor is composed. This space may be 4 inches, possibly 6 inches—sometimes more, sometimes less, according to the depth of beam. The concrete is generally composed of ashes and cement, especially when saving in weight is important.

Such a foundation is not of the substance required where there is a direct action thereon—as in the case of tile or mosaic floors—proceeding from the heavy and constant traffic usual in business buildings. Consequently such floors show the natural impact of the spongy concrete by numerous cracks, which, in the case of mosaic floors, can never be properly repaired.

This defect is not the only one of importance. A large percentage of the dampness usual in masonwork proceeds from this source. As this concreting is usually done just before the laying of the floors, it is quickly covered in, and dampness must pass through the wood-flooring in the process of drying-out. It is natural to suppose that kiln-dried lumber will absorb much of the dampness, and swell in consequence, so that afterward, when heat is turned on, it will shrink and open at every joint. More thought should be paid to a remedy for this, which may properly be termed a defect. Arches could be made that would reduce the space referred to, thus removing an element which, although it may not materially retard quick building, causes much of the criticism on the defective work (so considered) now credited to rapid methods of building. Other features no doubt enter into this class of building to which attention might be directed with profit to the builder, but it is hardly possible to discuss them in detail here. The individual experiences of others would be interesting and profitable.

Without co-operation on the part of the builder, the architect's suggestions are of no advantage, and the work lags in consequence. It is important, therefore, that none but the most reliable men should be selected to do the work. The architect, moreover, should make the selection, for if he is to come in for his share of censure in case of delay, it is better that he and his own men should wholly deserve it than that he should suffer for mistakes over which he has had no control. Should the whole work pass into the control of one firm (usually masons), it should be an arrangement satisfactory to the architects.

The architects of the Manhattan Life Building, Messrs. Kimball & Thompson, were ably assisted throughout, and they take great pleasure in publicly acknowledging their indebtedness to the different firms who aided them to make so remarkable a record.

The secret of success always lies in constant, unremitting push in every department. Begin at the very beginning ; an ounce of push at the start is worth a pound of push at the end. Start the trades whenever and wherever it is possible so to do, and keep up the tension ; then satisfactory results cannot fail to follow.

MANUFACTURES AND MATERIALS

THE OLD MEN'S REFUGE AT KAMLOOPS, B. C.

The Old Men's Refuge at Kamloops, Vancouver, B. C., from plans by R. Mackay Fripp, F.R.I.B.A., sketch of which appeared in a recent issue of the CANADIAN ARCHITECT AND BUILDER, has all its shingles colored with Cabot's Creosote Shingle Stains. These stains are used extensively on the Pacific Coast, and have repeated there their continuous successes in the east.

Messrs. Knowles & Co., of Avondale, have purchased for $10,000 from Messrs. Dill Bros., the plaster quarry at St. Croix, N. S.

The Beamsville Pressed Brick Company have recently been experimenting with a new brick machine, the invention of Mr. Sims, of Toronto. The machine is said to be capable of turning out from forty to fifty thousand bricks per day.

S. A. Lazier & Sons, of Belleville, Ont., have secured the sole right for Canada to manufacture the Norwich Folded Paper Floor Deafener, which has been extensively used by architects in the United States for building purposes with the most satisfactory results.

Mr. H. J. Warsup, Superintendent of the C. P. R. Cement Works at Vancouver, has recently experimented with British Columbia clay for the manufacture of cement, fire and building brick, etc. The experiments are said to have proved that in British Columbia there is to be found china and pottery clay in considerable quantities, and the necessary materials for the manufacture of plaster paris, fire brick, building brick and cement.

The Montreal Quarry Co., Limited, which has recently been granted incorporation, propose to acquire certain quarries in St. Denis Ward, Montreal, and to carry on the business of quarrying and selling stone. The quarries are upwards of two million feet in extent, are already fully opened up and well-equipped with plant. From them has been taken a large amount of limestone used in the public and domestic buildings in the city of Montreal. The provisional Board of Directors of the new company consist of Alderman Peter Lyall, P. A. Peterson, C.E., D. G. McCaskill, W. G. Reid and George McDougall.

CODE OF ETHICS.

THE following code, which is in conformity with the best standards of practice, has been adopted by the Boston Society of Architects:

Section 1. No member should enter into partnership, in any form or degree, with any builder, contractor or manufacturer.

Section 2. A member having any ownership in any building material, device or invention, proposed to be used on work for which he is architect, should inform his employer of the fact of such ownership.

Section 3. No member should be a party to a building contract except as "owner."

Section 4. No member should guarantee an estimate or contract by personal bond.

Section 5. It is unprofessional to offer drawings or other services on approval and without adequate pecuniary compensation.

Section 6. It is unprofessional to advertise in any other way than by a notice giving name, address, profession and office hours, and special branch (if such) of practice.

Section 7. It is unprofessional to make alterations of a building designed by another architect, within ten years of its completion, without ascertaining that the owner refuses to employ the original designer, or, in event of the property having changed hands, without due notice to the said designer.

Section 8. It is unprofessional to attempt to supplant an architect after definite steps have been taken toward his employment.

Section 9. It is unprofessional for a member to criticise in the public prints the professional conduct or work of another architect, except over his own name or under the authority of a professional journal.

Section 10. It is unprofessional to furnish designs in competition for private work or for public work, unless for proper compensation, and unless a competent professional adviser is employed to draw up the "conditions" and assist in the award.

Section 11. No member should submit drawings except as an original contributor in any duly instituted competition, or to secure any work for which such a competition remains undecided.

Section 12. The A. I. A. "schedule of charges" represents minimum rates for full, faithful and competent service. It is the duty of every architect to charge higher rates whenever the demand for his services will justify the increase, rather than to accept work to which he cannot give proper personal attention.

Section 13. No member shall compete in amount of commission or offer to work for less than another, in order to secure the work.

Section 14. It is unprofessional to enter into competition with or to consult with an architect who has been dishonorably expelled from the "Institute" or "Society."

Section 15. The assumption of the title of "Architect" should be held to mean that the bearer has the professional knowledge and natural ability needed for the proper invention, illustration and supervision of all building operations which he may undertake.

Section 16. A member should so conduct his practice as to forward the cause of professional education and render all possible help to juniors, draughtsmen and students.

THE PLANNING OF SMALL HOUSES.*

By T. W. F. NEWTON.

IN planning a small house it should be our especial study to avoid waste of space, and yet insure general utility. There must be no long passages; height must be kept down, and roofing as simple as possible. Breadth of effect must be studied rather than prettiness and ornament, as in this class of work there is no money to spare for either; all must be simple. One can hardly do better than conceive one's design on the lines of the old cottages in the immediate neighbourhood, as they will invariably suggest much in the way of simple planning, detail, and construction. It cannot in this connection be too clearly laid down that passage must be reduced to a minimum; this class of house cannot afford that to per cent. of its cost should be spent in passage. In large houses it is generally unavoidable but in small houses it can be so curtailed as to be practically *nil*.

The ground plan is the key to all the rest; if that be bad, as a rule all is bad; but it must be worked out by a careful consideration of the needs of the first floor. The front entrance should be fairly imposing, the door of ample width, with an inviting air about it. If it be a little lower than the usually given proportions, so much the better, as it will apparently increase the width. It is well either to have a porch or pent, or to recess the door, to afford shelter for anyone waiting to be admitted. Care should be taken that the front door be not too much raked by the principal windows. The door should open into a small lobby or outer porch, this in its turn should have a small cloak-room or recess for coats and hats. Three feet by three feet will hold a considerable quantity of these, and the general tidiness of the hall is thus preserved. Following this lobby an arched opening should give into a small hall of about 9 ft. by 12. This hall-sitting room, if carefully planned so that it may be shut off from the stairs and kitchens, will give quite a useful apartment. To secure this object it is advisable to have all the doors on one side, that the remainder may be free from traffic. An ingle-nook, if it can be arranged, or a corner fireplace will add to the picturesqueness of this cosy room. The ingle should always be low, never more than 6 ft. 6 in. or 7 ft., and a deep beam with a wide shelf over. An internal treatment of bricks gives a solid air of comfort, and wide benches at the sides add to this. The usual long passage hall is so much waste space, and quite useless as a room of any sort; neither can it be warmed. With this and the well of the stairs a current of cold air is generated which is drawn into the rooms every time the door is opened. If the stairs be shut off by a swing-door or a curtained arch, and a good fireplace given to the hall, an air of warmth and comfort is secured and greater privacy gained to the house, as the inmates may pass up and down unobserved from the hall.

The dining-room, if possible, should have an eastern aspect, and if it can also have a south light so much the better. The morning sun is always valuable in the dining-room in a house of this type, as it serves also as the breakfast-room, and the dinner is usually in the evening when the lamps are lighted. The chief points to be considered in this room are width, which should not be less than 13 ft. and ease of service to the kitchen and pantries—a small serving hatch from the latter serves a good deal of needless traffic. The fireplace is best at one end and the door at the other, at right angles to the fire. A long, low window, with a seat recessed, and a simple beamed ceiling should make a comfortable and useful room.

The drawing room, being more for afternoon and evening use, should face south to west. Here, I think, a square room is to be preferred—say 14 ft. by 14 ft.—with bays and ingle, and a plain ribbed plaster ceiling. There is a tendency to make ingle-nooks long, narrow, and high; this is out of character with the old traditions, as all old ones are just the reverse in every particular.

The kitchen should be of fair size, and the light preferably on the north or east side, so that the midday sun may not add to the heat. The windows should be at right angles to the fire, so that the light on the range may be unobstructed. The larder should have a similar aspect, and may open out of the scullery. The pantry is most useful near the dining room for easy service. The scullery should have sink and copper on the same side, under the window, and out of the draught of the door if possible; there should be two rows of 6 in. white tiles round the sink. The trades entrance and yard should be well away from the front door, and the space for coal and wood should be under cover and enclosed from the back porch. W. c. and ashpit are best distinct from the porch, and the former should not, as is too often the case lead out of the scullery. A small tool-house is useful for tools, stores of potatoes, etc. A good height for downstair rooms is 9 ft.

The first floor is gained by a light, easy, and wide staircase, alike convenient for all parts of the house, and the space underneath may be utilised for pantry or way to small cellar. The staircase, both up and down should be well lighted, and the landing so planned as to give easy access to four or five bedrooms, bath-room, box-room and w. c. Of the bedrooms, two should be of good size, and two or three smaller. A large bath-room with hot closet for airing linen is a great convenience; the shelves should be of open battens so that the heat may ascend. It is best to arrange the bath-rooms and w. c. over the scullery and outbuildings; by this means the circulation from the kitchen boiler is kept short, and breakages, should they unfortunately occur, do not cause so much damage.

The bedrooms must be arranged with an idea as to the position of the bed, so that it may be shielded from the draught, and give a view of the fire to anyone in bed. Strong light opposite the bed is to be avoided. The roof can be started at 7 ft. and go off to 9 ft. in the centre.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 5. MAY, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1895.

PRESIDENT	FRANK DARLING, Toronto.
1ST VICE-PRESIDENT	THOS. FULLER, Ottawa.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this Journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

IN the competition for a museum at Cairo, mention of which was recently made in these columns, 73 designs were submitted. The Technical Committee appointed to examine the designs, have recommended that no first premium should be awarded, as none of the designs came sufficiently near meeting the requirements. They further recommended that four designs which most nearly fulfil the requirements, should be awarded a premium of £225 each, and that the second premium be given to No. 62, by Mr. Trauchet. Nos. 8, 28, 33 and 71 are given honorable mention. All the awards go to French architects.

A COMPANY composed of leading citizens of Montreal is applying for incorporation for the purpose of perfecting arrangements for an International Exhibition to be held in that city from the 24th of May to the 31st of October, 1896. The local architects are already engaged on the preparation of designs for the necessary buildings. Mr. Joseph H. Stiles, who was a member of the Committee on Awards in connection with the recent California Exposition, is Director General of the enterprise. An effort will shortly be made to interest every section of the Dominion in the undertaking. The promoters have taken this definite action after having visited Europe, and satisfied themselves that Great Britain will exhibit. In view of the ability, financial and otherwise, of the gentlemen who have taken this important matter in hand; there is little reason to doubt its ultimate success. If successfully carried out it should prove to be of incalculable benefit to Canada. The present seems an opportune time, when the commercial depression is lifting, to successfully launch the enterprise.

ARCHITECTURAL competitions are of late becoming more frequent. There seems to be a growing disposition on the part of church and other corporations to secure designs in this way, the object being to get their work done more cheaply. The falling off in building enterprises, consequent upon the commercial depression, has been favourable to the growth of the competition evil. Architects with little or nothing to do, have been tempted to disregard the ethics of the profession, and to enter competitions, depending on the slightest possible hope that they would derive some benefit therefrom. The apparent willingness of a certain number of architects to enter these competitions, has not only helped to propagate the evil, but has encouraged the promoters to more and more disregard the rights of competitors in framing the conditions. As is illustrated by an article published on another page concerning a competition on the Pacific Coast, architects are now invited to submit designs in competition without any provision being made to secure a proper award. They are distinctly told that the right is reserved to reject any or all the designs submitted, and no guarantee is given that in the event of a design being chosen, the author will be given the carrying out of the work. In other words the competitor is asked to place himself completely at the mercy of a body of men who in nine cases out of ten have not the slightest knowledge of the proper manner of conducting a competition, and who want to be at liberty to do as they please regardless of the rights of competitors. May we be permitted to enquire to

what greater injustice and indignity architects must be asked to submit themselves, before they will consider the time has come to call a halt. We are glad to see that at least one member of the profession on the Pacific Coast has unmistakeably shown that he considers the time has already arrived. Every reputable member of the profession who desires to maintain his own self respect, the esteem of his professional brethren and the welfare of the profession, should fall into line.

NEGOTIATIONS have been in progress since the first of the present month between the Toronto Builders' Exchange, representing the master builders of the city, and the masons', bricklayers' and labourers' unions, with the object of endeavoring to arrive at a satisfactory understanding with regard to the rate of wages to be paid now that the five years agreement between these bodies has expired. A number of conferences have been held and an agreement has been reached as between the Exchange and the Labourers' Union, under which the rate of wages will be reduced by about 20 per cent., or from twenty-one cents to eighteen cents per hour. It is understood that the master builders have expressed their willingness to come to an agreement on the same basis with the bricklayers' and masons' unions. Indeed we have been informed that the delegates appointed by these unions to negotiate with the master builders have reported in favor of an agreement on these terms, but their report has thus far not been ratified by the unions. It is to be hoped that the unions will see the advisability of acting on the advice of their delegates in this matter. If the labourers' union, which is least able to bear a reduction in wages, sees the necessity for such reduction, there is the more reason why the better paid trades should fall into line. It is scarcely necessary for us to point out that during the last three or four years the stagnant conditions prevailing in the building trades have borne heavily upon employers and employees alike. The former have found it extremely difficult to secure contracts, and the competition has been such that in order to secure work, contracts have had to be taken at very unprofitable figures. The employees have suffered from lack of employment, but when employed, they were paid the same rate of wages as in prosperous times. The employers have therefore been under the double disadvantage of having little to do, and of being compelled to pay high wages on such work as they could secure, while being at the same time forced by the keenness of competition to take contracts at unprofitable prices. In view of these circumstances, it would be most unwise for the unions to endeavor to maintain the rate of wages which prevailed under the recent agreement. Everything except labor has been forced down in price. The manufacturer and supply merchant have alike been compelled to cut prices, until it is estimated that prices of materials to-day are from twenty to thirty per cent. lower than five years ago. The unions should take a common sense view of the situation, and agree at once to accept, say a reduction of twenty per cent. We cannot imagine that they will be so blind to their own interests as to attempt to enforce payment of the present rate of wages. The result of such action would be to negative the benefits which are in prospect for both employers and employees from the improved conditions which are now commencing to be felt. It should be remembered that the price of labor is governed to a considerable extent by local conditions. What these conditions have been in the city of Toronto it is not necessary to describe. So far as the master builders are concerned, while they are firm in their determination not to renew an agreement on the basis of the one which has recently expired, they have shown their desire to meet the employees on any fair and reasonable ground. The settlement of the matter now rests with the unions, as their acceptance of the twenty per cent. reduction agreed to by the labourers' union will adjust matters for the present year at least. We do not believe that the master builders will be willing to again enter into a long term agreement, as their experience under the last one clearly demonstrated that the advantage of such an agreement is largely on the side of the employee. As has been pointed out, the employers were forced by this agreement to pay a much higher rate of wages than the conditions warranted. A point which should be guarded in any new agreement which may be entered into is, that the unions should bind themselves to expel any member of their organization who shall undertake contracts on his own account, and thus enter into competition with the legitimate master builder. It is understood that this is an evil from which the employers have suffered to a considerable extent during the recent depression.

THE ROYAL CANADIAN ACADEMY EXHIBITION.

THE architectural section of this exhibition has for the first time formed an important part of the exhibition. Even so, the profession is not widely enough represented. The drawings are nearly all by a few well-known Toronto men. Of members of the Ontario Association not residing in Toronto, there is but one exhibitor of original design, Mr. Fred. Henry, of London, and a couple of English sketches by Mr. W. L. Munro of Hamilton. Outside of the Ontario Association, there are but three exhibitors :—Mr. W. C. Harris, of Charlottetown, P. E. I.; Mr. A. T. Taylor, of Montreal, and Messrs. Clift & Pope, of Montreal, who sent in a set of competition drawings, which, contrary to the rules of the exhibition, were unframed, and were hung only at the request of the Ontario Association.

It can hardly be said, that the greater part of the drawings exhibited were exhibition drawings at all. They seemed to be, for the most part, office perspectives, made at any time in the last few years to show clients how their work would look, or to give the boys in the office practice. We would be the last to advocate a practice of misspending time in making pretty drawings of buildings, but on a special occasion of this kind, which is intended to appeal to the general public, who only understand a picturesque representation, a little of the spirit of the shop window architect, would have been in order. Canadian architects are always threatened by the idea that important work is best entrusted to an American architect from a larger city than Toronto, and it would be serviceable to the profession to make a good show occasionally, such as the public can understand. It is, however, apparent from this exhibition, that the important work which is being done now is in the hands of Canadian architects.

The largest piece of work is the Brockville Lunatic Asylum, designed by Mr. Tully, and recently completed. The perspective is on so small a scale that it needs a little calculation to convince the mind of its real extent, which must be at least 1,000 feet in length. There is, of course, repetition of pavilions, but the variable remainder is still of great extent. Mr. Tully also exhibits the original perspective of Trinity College—an old fashioned sepia drawing—and thus brings together what was probably his first and his most recent, though we hope not his last, great work. In the drawing of Trinity there appears a stone parapet wall to the terrace which was not executed, unfortunately it seems to us; the decisive base thus given to the building would have contributed greatly to its dignity. It is always difficult to have an adjunct of that kind executed at once, unless there is a consideration of pure utility to recommend it, and they appear to have been contented with a grass embankment at Trinity.

Next in size come the competition drawings of Messrs. Siddall & Baker and Mr. J. F. Brown, for the Legislative Buildings of Victoria, B. C. It is impossible to criticize these buildings fairly without the plans, but the plans would probably justify us in a suspicion of over windowing in parts. Mr. Brown's use of Romanesque forms is original and interesting, and without any of the brutal quality which, as in the case of the Ontario Parliament Buildings, is so often associated with that style. Of other large work, Messrs. Strickland & Symons' new Union Station, Toronto, has already appeared in the CANADIAN ARCHITECT AND BUILDER, is now sufficiently near completion to be a familiar object to Torontonians. It is modelled on an American type exemplified by the Illinois Central Station, at Chicago, but is a better design, and has had the peculiar difficulty of amalgamation with the old station, a difficulty which with that proceeding from the different levels, appears to have been skilfully met. The drawing by D. A. Gregg, about 3 × 5 feet in dimensions is a model of clear, serviceable perspective rendering, and should be studied by draughtsmen.

Mr. Lennox's design for the proposed new hotel, the next large piece of work, is also a beautiful drawing—indeed the drawing itself has so much claim to be considered as a work of art, that the tendency is to consider it apart from the design, and turning to Mr. Gregg's plain rendering of the Union Station which hangs next on the wall, one is compelled to admit

that it carries greater weight. Nevertheless, Mr. T. R. Johnson, who has signed a companion drawing of Mr. Lennox's Beard Estate Building, and is obviously the author of this, is to be congratulated upon a clear evidence of unusual talent. As to the hotel, if Toronto capitalists can build it, and Toronto's attractiveness can support it, we shall be very glad to see it. It may be questioned whether the received idea that hotels should be designed with some frivolity is correct, but this granted, the design in question is excellently carried out, amazingly so, when we consider that the style in which Mr. Lennox has worked out his large buildings, hitherto, is anything but frivolous. As a matter of fact, one feels sure that the gracefully projecting consoled cornices of this style mean galvanized iron, and sadness draws a veil over enthusiasm.

Mr. Burke's Simpson building of last year, now "the old Simpson building," will, we may suppose, be repeated in the more extensive new Simpson's building, which is about to rise from ashes. The problem, a packing box full of windows, is an exceedingly difficult one, and Mr. Burke had succeeded in giving a dignified solution without in the least entrenching upon the first requisite of such a building—abundance of light. Indeed the very determination to fulfil the conditions perfectly saved the design. Being full of light from top to bottom, the usual abrupt transition from solidity to plate glass is avoided, and though the show windows are unusually wide, the effect is unusually solid.

There is a design for a store front by Mr. Wickson, which, although it has a central gable brought by a pier plump down upon the middle of the girder, shows how suitable the mullioned gothic he has employed is for this kind of work: how much more suitable than the classic handling which has always prevailed. The English architects have now gone to Belgium in search of a style and the example has already made itself felt in this country and more of the same may be expected. If instead of looking merely for style our shop front designers would take a hint from the Flemish they ought to find the most characteristic fronts, which are simply mullions and glass from end to end, serviceable models for a store which is to be well lighted on each floor.

There are several other public and commercial buildings of various kinds which should be mentioned. Mr. Taylor, of Montreal, shows drawings of a new wing to the Art Gallery at Montreal, and the Notre Dame street branch of the Bank of Montreal, both of which are designed with knowledge and also well drawn. Mr. Taylor is evidently facile with his brush and has sent besides his own designs some water colour sketches of old buildings in Europe.

Messrs. Clift & Pope's design is a good commercial front.

Mr. D. B. Dick exhibits a photograph of the University Library and drawings of the interior of the library reading room and of the gymnasium. The stack room is the most interesting because the most straightforward part of the library. This cause and effect relation never fails. When will it be recognized as the only sure road to success?

Mr. Lennox's Athletic Club is a building of multifarious uses and has no leading motive such as the massive Romanesque requires. It is not a style that descends readily to the trifles of daily life.

The free handling of classic in Messrs. Gordon & Helliwell's competition drawing for the art gallery of Milwaukee is good.

Mr. Gouinlock's sketch for the Sheppard Publishing Co.'s building makes one hopeful for the coming Foresters' building.

Among the designs for churches, Mr. W. C. Harris, of Charlottetown, seems to have enjoyed the best opportunities and exhibits designs in a scholarly style for two handsome cut stone churches at Charlottetown. The interior of one of them is also exhibited and shows an octagonal crossing with the ceiling level with the nave and transepts, and showing outwardly as a small pyramid on the roof. A plan of this church would have been interesting.

Mr. Townsend has two very charming country churches which look to our mind as perfect in their way as any work of the living periods of church building. The wooden spires which make no profession of being stone and the country simplicity of other details do not impress one in the first place with their originality, they seem so fitting, but a closer inspection shows that this is original work of the first quality.

Mr. Darling who seems to be the church designer par excellence shows as great originality in another way. The examples shown, more costly than Mr. Townsend's, compare more directly in detail with old work, but the work is not so much an adaptation of gothic as an appropriation. It compares with old work but is essentially of our own generation. The modern multiplication of conveniences and the requirements of our climate, usually evaded by a designer or concealed under the exterior of an ancient church which had none of them, all appear as features in Mr. Darling's design and the result is that his churches have a touch of the same more highly organized character that distinguishes our modern domestic work from that of former periods. The type is thus somewhat altered but the gothic feeling is perfect and the variety and interest of the features increased.

It is precisely this more highly developed modernness that most of the other designs lack and which chills interest in them not only in spite of their "correctness" but because of it, for it is not correct now.

Mr. J. F. Brown opens up another question in a well worked out design for the Chester Mission of the Jarvis Street Baptist church. At first sight this appears to be a pretty little Anglican church with an apsidal chancel. The plan, which is inserted on a smaller scale, shows that what appears to be a chancel is in reality the infants' department at the entrance end of the church, the opposite end from the pulpit and choir. Is this good designing or not? It is an adaptation of an old external form to an internal use to which the old form is perfectly suited. Instead of looking upon it as a chancel clapped on to the wrong end of the church, we may consider it as an expansion of the apsidal baptistry which was common at the entrance end and was like this devoted to the young. Nevertheless the design is disturbing. The natural man abhors it but has no arguments. The truth probably is that whereas the chancel was the glory of a church, this infants' department is a mere adjunct, to be connected with the church occasionally by opening folding doors, and the real centre of interest, the pulpit and its surroundings, has probably no external expression but a flat wall and some little useful windows for the baptismal vestries, so that the design is in reality, turned round, proving once more the futility of imitation, even the cleverest.

Space fails to comment upon the dwelling house work, and indeed there are but few designs and no plans except on one of Mr. Townsend's drawings. There is little satisfaction in either looking at or discussing a dwelling house without knowing its plan. That which Mr. Townsend has shown for a $4,000 cottage in the country, is an admirable piece of work, and is carried out in elevation with the refinement and simplicity of true design. Scientific house planning is a study of our own days, and although the present exhibition is not strong in this class of work, it is satisfactory to know from papers that have been read in the Architectural Societies and printed in this journal, that the mind of the profession in Canada is turned towards its study; for it is the principles which have found acceptance in this branch of design that will be at the bottom of all true advance in architecture.

QUESTIONS AND ANSWERS.

H. Bros., Kincardine, Ont., write: We want to build a brick chimney 80 feet high, square chimney. What size should the base be for this chimney, and should cement or mortar be used.

ANSWER.—It will depend largely upon the nature of the soil upon which the chimney is to be built, as to the dimensions at the base. If built on clay soil, allow about three tons to the square foot; if on sand, about four tons to the square foot. You should take into consideration also, the thickness of the walls. Unless the chimney requires to be rapidly constructed, the use of cement mortar is not necessary; a good quality of ordinary mortar will be sufficient.

PERSONAL.

Mr. R. McKay Fripp, F.R.I.B.A., of Vancouver, has lately returned from a visit to Europe.

Mr. Edward Elliott, architect, Halifax, N. S., has recently associated with him in his practice Mr. Chas. H. Hopson, of Washington, D. C. The firm will hereafter be known as Elliott & Hopson.

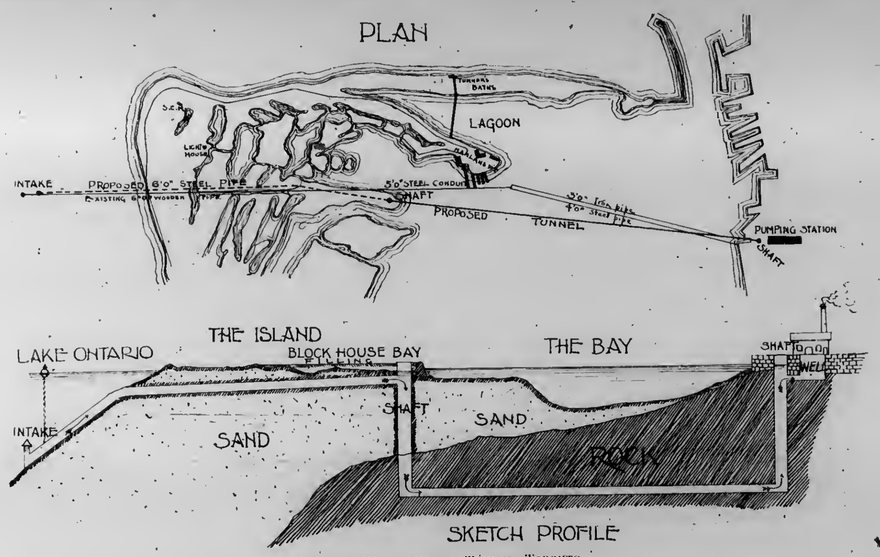
The death is announced at Hamilton, of Mr. Hiram King, who was engaged on the construction of the Desjardins Canal, Great Western and Hamilton and North-Western railways. Mr. King has resided in Hamilton since 1861. He was in his ninety-second year.

PROPOSED WATER WORKS TUNNEL.

So far as Toronto is concerned, her citizens will have a large interest in the proposed water works tunnel, an illustration of which is here given. The question of pure drinking water is one that calls for the best consideration of the people of every municipality, for it has been thoroughly established, and Toronto has had some bitter experience in this respect, that drinking water may be made the vehicle for conveying some of the worst forms of contagious disease.

How to remove the constant defects that have occurred in the Toronto Water Works system, has been a serious question with aldermen, City Engineer, and most thoughtful citizens, for years. The construction of a tunnel, as is now proposed, will, it is believed, prove a solution to these difficulties, and in the building of this tunnel, readers of the CANADIAN ARCHITECT AND BUILDER, whether residents of Toronto or not, will have a practical interest from an engineering standpoint.

As shown in the illustration, a shaft will be sunk at the pumping station of the Water Works, Toronto, to a depth of, at least, 100 feet, and it may be found necessary to go from 25 to 50 feet deeper. The diameter of the shaft will be 10 feet. Across at the Island, at what is familiarly known as Block House Bay, a second shaft of the same depth will be sunk. The length of the tunnel will, in round figures, be 6,000 feet, and 6½ feet diameter, running clear through the rock that is struck below. This rock partakes largely of the character of shale, but at the depth named is found to be of a very rock-like nature, hard and durable. The shale seams run parallel with the proposed tunnel, so that no trouble, or caving in, is anticipated in the construction of the work.



PROPOSED WATER WORKS TUNNEL, TORONTO.

Commencing again about 11 feet down in the second shaft, a steel pipe will be extended along to the intake, connecting there with another pipe, which, if the by-law is sanctioned by the people, will also be of steel. The pipe will be laid on a very slight incline, entering the intake at a depth of about 12 feet below the surface, and representing very much the appearance of water in a glass tube. The cost of the proposed steel pipe in the horse shoe shape, going into the intake, will be $75,000, and whilst its construction does not necessarily depend on the construction of the tunnel, yet it will form part of that work if the entire scheme is endorsed by the people. The total cost of the entire tunnel, including the new intake pipe, will be $525,000, and will be made to provide for the requirements of a city of 700,000 population.

The methods employed in tunnel building have changed so largely in recent years that the difficulties common in projects of the kind a quarter of a century ago are altogether unknown to-day. What with the compressed air rock-drills, steam and electric rock-drills, and the employment of high explosives, almost any reasonable scheme of tunnelling or excavation can be easily and successfully carried through. So important have been the developments in engineering science, that it is said a famous engineer once declared that he would undertake to tunnel straight through the earth from New York to Pekin, if the necessary capital would only be forthcoming. And yet, it is worth remembering that one needs only to go back 25 years to find that all tunnelling was done with hand-drills and gunpowder blasting. In the Toronto Water Works tunnel compressed air-drills will be used, and the nature of the rock at a depth of 128 feet having been examined, a sample of which is to be seen at the office of the City Engineer, this officer believes the way is clear for an easy completion of the work, when once entered upon.

The first important sub-aqueous tunnel was that under the Thames river, which was projected in 1798, but was not completed until 1843. It is believed that the Toronto tunnel can be completed inside of 18 months. Under the St. Clair there is a tunnel 6,050 feet long; under the Severn, one over four miles long, and the Mersey tunnel is 23,615 feet long, all completed within a reasonable period, so that it will be seen there has been good progress made in the construction of sub-aqueous tunnels, as well as in other directions of tunnel building, of late years.

Besides, in arriving at a correct estimate of the time for building the proposed tunnel, Toronto's Engineer has also other experience to guide him in arriving closely at the cost of the work. He has only to cross the lake to Rochester, N. Y., and there secure data of the cost and methods of building a tunnel of a similar character to that proposed by Toronto. Milwaukee also turns in its experience, whilst information is readily secured from other cities and municipalities.

In the building of the two shafts of the Toronto tunnel, either brick or concrete will be used. The latter would probably be the cheaper, but if, in its use, it should be found that defects showed themselves, then the resort would be to brick. The leading idea of the plan is to give Toronto a permanent work and after the amount of temporizing, at a terrible cost to its citizens, that has been indulged in, it seems reasonable to suppose that they would welcome something of a more enduring nature.

BRICK FOR STREET PAVEMENTS.

THE recommendation of City Engineer Keating, of Toronto, that $80,000 be expended in brick pavements, has, naturally, led to enquiries as to the wisdom of the suggestion, and should it be carried out, of the ability of brick manufacturers to meet the demand. Interest in the matter is accentuated from the fact that the Council of the City of London has had this question under consideration, and recently sent a deputation to leading American cities to make enquiries as to the utility of brick pavements. Winnipeg is also giving thought to the question, so that altogether brick for street pavements is becoming an active municipal problem.

At all times the subject of road-making is an important one for municipal bodies, and students of municipal engineering, though opinions and experience differ widely in different countries. In Great Britain, Germany, and other continental cities, wood paving is growing in favor, recent investigations in Berlin, that had been conducted with a thoroughness characteristic of the German people, and extending over a period of fifteen years, resulting in a verdict decidedly favorable to wood paving. In Canada and the United States, municipal bodies have shown a growing dislike for wood pavements. For a decade and more past, opinion has been growing in favor of asphalt, with brick, during more recent years, finding many strong advocates.

For street paving in Toronto brick has been very little used, though it may be news to not a few to learn that the following streets are paved with brick: Dundas street, from the bend to Lansdowne avenue; Lansdowne Ave., from Dundas to College; College, from Lansdowne Ave. to Bathurst; Bathurst, from Queen to Bloor, the pavement being laid between the street car rails only, and has been down about two years. Besides these streets, to a limited extent brick has been used for pavements in a few private lanes, and yards, where heavy traffic occurs. Just at the present time a lane in connection with the Gas Company's works, in the east end of Toronto, is being paved with brick by Messrs. Taylor Bros., of the Don Valley. This is in the line of an experiment, in anticipation of brick coming more widely into use for street pavements. Outside of these local instances, if we except a brick pavement on one of the main streets in the town of Chatham, laid in 1890, brick, as a paving material, has not been used in Ontario.

What is to be said in favor of brick paving? Contrasted with asphalt, it is claimed that it is less noisy. The objection against asphalt, because of its slippery nature in winter, rendering driving, in a measure, dangerous, will not hold good with brick so its friends allege, from the fact that horses are able to secure a foothold in the small spaces between the bricks, and this prevents their slipping. In point of sanitation brick and asphalt hold about the same position. Where necessity compels the tearing up of the road to effect repairs in gas mains, water pipes, and so on, bricks are more easily removed and replaced than asphalt.

If brick, however, is to come into active competition with asphalt the decision will rest largely on the price, and the ability of manufacturers to make a brick of the needed quality, and evenness throughout. The bricks used on Dundas, College and Bathurst streets were imported from the United States, and cost, laid down, from $20 to $23 per thousand. About half of this amount was represented in freight and duty. With bricks manufactured in our own country, this cost ought to be largely reduced, and yet, as we understand the temper of those who have looked into this matter, the cost would need to be brought down to about $12 a thousand, if the argument of cost of brick, as against asphalt, is to prove an important factor.

Are Canadian brick manufacturers in a position to make a satisfactory brick for street pavements, and in sufficient quantities to meet a large demand from leading municipalities? Why not? In the Don Valley and at the Humber, experts say that shale exists in abundance, suitable for making a good paving brick, so that Toronto is favorably situated for a brick industry. Mr. C. R. S. Dinnick has entered into the manufacture of vitrified brick at his manufactory, near Toronto Junction, and like others, looking forward to brick, coming into increased use for pavements, he has been putting himself in shape to meet a demand in this direction. In tests of vitrified bricks, made by Mr. C. H. C. Wright, of the School of Practical Science, Ontario bricks held a creditable place in contrast with bricks of well-known manufacturers in the United States.

It would seem, therefore, that there is much to be said favorable to brick paving, and if leading cities, like Toronto, London, and Winnipeg, are going to embark on work of this nature, there is encouragement for the extension of brick manufacture in Toronto, and other parts of Ontario.

OUR PUBLIC PARKS.

THE city of Toronto can boast of as many natural beauties of scenery in its parks and ravines, with their numerous glades and dells, as any large populously inhabitated centre can wish. The Torontonian is, generally speaking, proud of his city, and in all matters connected with municipal government is a law-abiding subject. There is one feature, however, in which his perversity and want of decorum may be said to earn for him the appellation, sometimes applied by provincial papers, of "hoggishness," and that is the determined way in which all these natural beauties are neglected and abused.

The condition of our public parks is deplorable. Apathy on the part of those charged with their proper maintenance leads the public to conduct itself in a manner which can find no parallel in any city of the size of ours. There is hardly a strip of boulevard which is not wantonly injured. The proper crossing place, or the appointed portion of sidewalk, is not put to its proper uses: a line across the grass is the rule. The earnest appeals of householders, who desire to keep their lawns trim and neat, are disregarded, and in public parks the rule is to avoid the path and spoil the sward.

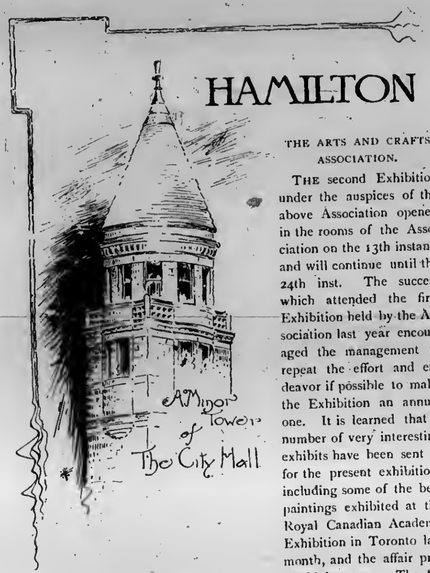
The Horticultural Gardens, which for many years were a most attractive place of resort, are spoiled by numerous tracks cut across the grass to the Pavilion. There is no necessity for shortening the distance from the Carlton street gate to the Pavilion; the beautiful broad walks, with their flower-flanked borders, are much more pleasant walking; the use of them will permit of the beautiful sward being cultivated, which has always been the charm of this pretty little breathing space, whereas, the well beaten track across the grass is worse than an eyesore. In the Rosedale ravines, and those passing northward to Reservoir Park, there lie attractions innumerable for the opening up of lovely vistas, of charmingly wooded hill sides, gracefully curving drives, and glimpses of scenery overhead and in front, as one would traverse them, were they put to a proper and suitable use.

But what of the Queen's Park? Is there a citizen who can visit another town or city without being ashamed and humiliated as he thinks of the condition of this park? The limited area for a public park which existed a few years ago has been sadly encroached upon by the erection of huge piles of stonework, till little of the ground seems to be left, and what remains is in a state of disorder, which is shameful to those charged with the maintenance of the grounds. Not only this; the conduct of the public in crossing the sward in every direction to make a cut-off, thereby breaking down fences, encroaching on boulevards and private property, has made the Queen's Park one of the most neglected and pitiable sights anyone would wish to see. No truly loyal citizen can take a stranger through the park with a feeling of pleasure. We spend large sums of money in advertising the advantages of the city, enumerating amongst other things its natural beauties. Can we call the Queen's Park one of them?

How do we compare in the maintenance of our public parks with such cities as Montreal and Halifax? The latter city, with a population of one-quarter of ours, has a public park which is a delight to all who visit it; whilst a visit to Montreal in summer makes one come home with a heavy heart to contemplate decay and ruin in every part of Queen's Park.

There are several associations who are interested in promoting the prosperity of the city for directly financial reasons. These of themselves are powerful enough to cause some immediate action being taken to mend the existing condition of the park, could they be induced to do so. They would soon receive the assistance of other associations, whose artistic pursuits and education would be invaluable in restoring to its natural beauty one of the most picturesque plots of pleasure ground any city can wish to possess.

Mr. G. Ernest Fairweather recently delivered a lecture on "Art and Architecture," at St. John, N. B.



HAMILTON

THE ARTS AND CRAFTS ASSOCIATION.

THE second Exhibition under the auspices of the above Association opened in the rooms of the Association on the 13th instant, and will continue until the 24th inst. The success which attended the first Exhibition held by the Association last year encouraged the management to repeat the effort and endeavor if possible to make the Exhibition an annual one. It is learned that a number of very interesting exhibits have been sent in for the present exhibition, including some of the best paintings exhibited at the Royal Canadian Academy Exhibition in Toronto last month, and the affair promises to be even more successful than the one held last year. The Association is doing excellent work, and is deserving of every encouragement at the hands of the citizens. It is one of the few institutions of the kind in Canada that have achieved a satisfactory measure of success, and should therefore be an object of pride to the city in which it is located.

The Association was originally founded in October, 1885, by a contribution of $50 each from fifty individual citizens who felt an interest in matters artistic, and in the improvement of handicraft on the part of mechanics and amateurs. The Association is held in high esteem by the artizan classes, inasmuch as it aims to enhance artistic skill and to insure public recognition to the artizan who produces meritorious work. At the Exhibitions of the Association the name of the artizan takes precedence of that of the firm with which he may be employed in connection with any exhibit of his work. This is a distinct departure from the method pursued at the various industrial exhibitions held throughout the Dominion. At these the name of the artizan is conspicuous by its absence. All exhibits are made in the name of the manufacturer, and no recognition whatever is given the skill of the artizan. The result of the different method pursued by the Arts and Crafts Association has been to stimulate artizans in various lines of manufacture in this city to put forth their highest skill, knowing that their name and work would

PUBLIC LIBRARY BUILDING, HAMILTON—HEADQUARTERS OF THE ARTS AND CRAFTS ASSOCIATION.

have to bear public criticism. The tendency has been towards bettering the position of the painstaking and skilful workman, while employers vie with one another in exhibiting the products of their manufactories and the skill of their workmen, and the public are educated to know and appreciate a good article, so that the result from every point of view is most gratifying.

During the past winter the students in attendance at the classes of the Association have not only had the benefit of trained instructors, but have listened at intervals to papers by practical men on such subjects as "Stained Glass," "The History of Architecture," "Wood Carving," "Furniture," etc. The subjects taught may be classed under the following heads:—Freehand, model, crayon, geometric, architectural, mechanical, perspective and memory drawing; shading, painting (oil and water color) from copies, casts and nature: painting portraits from life; modeling in clay or wax; wood carving; art needlework; casting; etching on copper; engraving; lithography; pen drawing for illustration; designing, as required for all industrial pursuits; practical plane, solid and descriptive geometry; architecture and engineering, with subsections of the same.

Students are privileged to work in the school seven or eight hours daily under an instructor who sees that no time is wasted, and can compete in about twenty-five sections, or study for medals and certificates granted by the Education Department of Ontario. A Sketching Club is organized during the summer vacation, each member paying a small entrance fee. The total amount of these fees, less postage, etc., is refunded to the members in the form of prizes. There is also in connection with the School an Art Literary Society. The efficiency of the

WALL PAPER DESIGN AWARDED DIPLOMA AT THE WORLD'S FAIR.

School may in some measure be judged by the fact that in the competition for scholarship at the Ecole des Beaux Arts, in Paris, whereat hundreds of the best students from all parts of the world competed, Mr. John Lyle, a late student of this school, took the third place in the Art subjects, and fifth place in modelling in clay, and gained his admission to what is considered the most advanced art academy known.

Mr. S. John Ireland, the Principal of the School, is exceptionally well qualified for the position he occupies, having had an unusually varied experience in the art and technical schools of England. It is a rare thing indeed to find a man who, like Mr. Ireland, has a practical knowledge of subjects so widely different from one another as water-colour drawing and machine design. Mr. Ireland is enthusiastically interested in the work in which he is engaged, and can be depended on to bring the efficiency of the school up to the highest possible point compatible with the means and appliances at his disposal.

There is one feature in connection with the institution which is open to criticism. The work of the students is judged by the Education Department of Ontario, which exercises control over the so-called "Government Art Schools" of the Province. If I am rightly informed, the names of the persons appointed to judge the merits of the work of the students are not disclosed, and there is no guarantee to the public that they are qualified for their duties. This fact has a tendency to weaken public confidence in the work of these institutions, and to limit the attendance and ambition of students. It is a well-known fact that the gentleman under whose control these art schools are placed has had no training for the position, and this fact has greatly retarded their success. If it is the intention of the Government to continue the yearly grants to these schools, they would do well to place them under control of a thoroughly qualified superintendent, and appoint equally well qualified persons, whose names should be given to the public, to pass judgment on the merits of the pupils.

In the ARCHITECT AND BUILDER for June some details will be

given of the Hamilton Arts and Crafts Association Exhibition now in progress.

ARCHITECTS' GRIEVANCES.

The local architects are complaining of the increased competition to which they are being subjected by builders. In most cities of Canada it is understood that the preparation of architectural plans and designs is finding its way more and more into the hands of properly trained architects, but in this city the opposite seems to be the case; the disposition of owners of property seems to be to dispense with the services of an architect in the belief that by so doing his fees can be saved. It is well known to those familiar with the subject, that the cheapest work often proves to be the dearest in the end, but most persons look only to the present advantage. The peculiar condition prevails in this city of builders entering into competition wherever possible with architects, and at the same time where the latter have work to be done, expecting the privilege of tendering upon it. An instance is cited in which an architect prepared designs for a building, and after calling for tenders was compelled by the owner to modify them in order to reduce the cost—again called for tenders with the result that the cost was declared to be still too high, and finally had the work taken out of his hands entirely and turned over to a builder. These are the kind of things with which Hamilton architect are contending at present, and some of them are in consequence feeling far from satisfied with their lot.

LEGAL.

THE case of the Royal Electric Co. v. Wand, and Wand, Plaintiff in Warranty, v. Walbank, decided in the Montreal courts recently, is one in which architects and contractors will doubtless feel an interest:

On the 17th April, 1889, a contract was entered into by which the principal defendant, Wand, undertook to build a brick chimney for the electric station of the principal plaintiff, at a fixed price of $3,300, and according to certain drawings and specifications made by the defendant in warranty (who as architect was to be the depositary thereof) in a good workmanlike and substantial manner, to his satisfaction and under his direction. In May 1893, the principal plaintiff instituted an action against the contractor, alleging in effect that the contractor had not built the chimney according to the rules of art, and that by reason of defects in its construction it had deteriorated to such an extent that it had been condemned by the city Building Inspector and by other skilled persons, who were of opinion that it would have to be partly demolished and reconstructed on a different plan; that in consequence it was taken down to the point indicated in the report of these experts, and reconstructed according to their advice, at a cost of $1,116, apart from the experts' fees, which amounted to a further sum of $165, making altogether $1,281.04. By the present action in warranty the plaintiff in warranty alleged in effect that he was not responsible to the principal plaintiff in the present suit, but if there was any responsibility, the same must fall upon the defendant in warranty as architect; that the plaintiff in warranty, as contractor, had carried out the drawings, plans and specifications with great care and in a workmanlike manner, with the best of materials, to the satisfaction of the architect, and that if any damages had arisen they had been caused by the faulty plans of the architect, and the responsibility must fall upon him. The defendant in warranty pleaded, first, a demurrer which was dismissed. Secondly, a plea to the merits, alleging in effect that the plans and specifications were correct and sufficient according to the rules of art in every respect, and the defects in the chimney were due to the fact that the contractor did not follow the plan nor carry out the specification provided for his guidance in certain respects pointed out in the plea. The plaintiff in warranty answered saying that he conformed to the plans and specifications, and to the instructions he received from the defendant in warranty, and that the work was done under his supervision. The principal defendant pleaded to the principal action, stating in effect what he had alleged in his action in warranty. The principal action was tried alone, and the principal defendant was condemned to pay the principal plaintiff the sum of $1,281.04, representing the cost of taking down and rebuilding the chimney according to the report of the experts. The court held that the plaintiff in warranty had failed to prove the material allegations of his declaration, and particularly that he constructed the chimney in question according to the drawings and specifications of the defendant in warranty, or that the damages resulting from the manner in which the chimney was built were caused by any defect in the drawings or specifications. The court held that the drawings and specifications were correct and sufficient and in accordance with the rules of art; that there was nothing unusual about them, or there would have been no difficulty in constructing the chimney in question in accordance therewith, and that, in fact, numerous chimneys had been constructed according to specifications substantially the same. The court further held that the plaintiff had departed from the drawings and specifications in several important and material respects. Instead of the inner wall or core of the chimney being carried up to the point indicated on the plan, and there united with the outer wall, it was carried up and united with the outer wall about 16 feet higher at the spring of the arches, and it was proved that this was the cause of the weakness of the chimney, and that the chief failure and defect in the chimney occurred at the place where the plaintiff united the wall, contrary to the defendant's plan. There was also a defect as to the holes for ventilation. The plaintiff in warranty should have consulted with the defendant in warranty, and followed his instructions if he did not fully comprehend the specifications. The weight of evidence went to establish that the damage to the chimney was not caused by wind pressure, but by the expansion of air, and that what contributed most to the cause of damage was the carrying up of the inner wall, and the failure to provide proper ventilation and to properly bond the chimney as required by the specifications. Upon the whole, the court came to the conclusion that the action of the plaintiff in warranty must be dismissed.

THE COMPETITION EVIL.

WE have received from Mr. Edw. Mallandaine, architect, Victoria, B. C., the following copy of a notice which recently appeared in the Pacific Builder, of Portland, Ore., and of a letter with reference thereto addressed by him to the Board of Supervisors:

NOTICE TO ARCHITECTS.

The board of supervisors of the county of Santa Cruz, state of California, ask for plans and specifications in detail for a county courthouse to be built on the lot owned by the county situated on the corner of Pacific avenue and Cooper street in the city of Santa Cruz. Two plans are asked for, one for an iron and steel fire-proof building, and the other a brick and stone combination. The building to consist of two storeys, and to be designed to provide for a courtroom and other rooms for offices for all the county officials, as well as a room for the board of supervisors, save and except an office for the county recorder, together with vaults for the county treasurer and county clerk, the necessary toilet rooms and other accessories to a building of that description. The cost of said building not to exceed $40,000. Plans and specifications will be received up to April 22, at 10 a. m. Each plan must be accompanied by a certified check for five per cent. of the estimated cost; conditioned that the architect whose plans are accepted will give good and sufficient bond that the cost of erecting said building shall not exceed the cost mentioned in his plans and specifications. All plans must be in black and white and addressed to the clerk of the board. The board reserves the right to reject any or all plans and specifications submitted. Ed. Martin, clerk.

(COPY)

VICTORIA, B. C., April 13th, 1895.

The Board of Supervisors for the County of Santa Cruz, Cal.
Ed. Martin, Secy.

SIRS,—The unmitigated insult to the profession at large set forth in your "Notice to Architects," (Pacific Builder) causes me to write and ask which of the two parties is more fit for Stockton—the one who drew up the notice or the lunatic at large who would act on it. The unblushing effrontery displayed is only equalled by the ignorance shown of all professional, not to say, business dealing.

I am, Sirs, &c.,
EDW. MALLANDAINE, Architect.

In placing the above material at our disposal, Mr. Mallandaine remarks that "it will show that at least one architect is to be found who can resent an insult to the profession."

MANUFACTURES AND MATERIALS

Mr. Theophile Girouard, St. Catharines, Ont., has patented an exterior finish for frame structures.

The Albert Mfg. Co., of Hillsborough, N. B., are making large shipments of their goods to Ontario.

The Gurney Stove & Range Co., limited, is applying for incorporation in Manitoba, with a capital stock of $50,000.

A handsomely printed and elaborately illustrated catalogue has been issued by Messrs. A. B. Ormsby & Co., 126 Queen St. east, Toronto, descriptive of their metal ceiling, wall decorations, etc.

The Metallic Roofing Co. of Toronto have issued a neat catalogue for 1895, illustrating their various brands of roofing, sheeting, corrugated iron, etc. Several illustrations of buildings on which their goods have been used are also published.

A sample of pure limestone from a quarry which is about to be opened at Lake Manitoba, is being exhibited at Winnipeg. The quarry is about 56 miles from Winnipeg. The stone will be conveyed by barges to Westbourne. The material is said to be very easy to work, and that on this account it will be able to compete with Selkirk sand-stone.

An order has been given by the Courts for the winding up of the British Columbia Pottery & Terra-Cotta Co., Limited. The company was incorporated in September, 1890, with headquarters at Victoria, and a nominal capital of $60,000 divided into 1,000 shares of $60.00 each, of which about $36,000 have been allotted and paid up in full. A liquidator will be appointed.

Mr. Wm. V. Williams, of Winnipeg, is about to commence the manufacture of a patent pressed brick, manufactured by a chemical process, and which, he claims, will revolutionize the existing order of things in the building trades. The brick, which can be made in any colour is said to be suitable for a variety of purposes, and to be cheap and durable. A company to manufacture is said to be in process of formation.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

At the last meeting of the Council of the above Association, Messrs. Resther and Findlay were appointed to the vacancy in the Council due to the retirement of Messrs. Dunlop and Gauthier.

THE ONTARIO LEGISLATIVE BUILDING.

THE Gazette of this city recently contained the following :—The complaint is made that the acoustics of the new Ontario Legislative chamber at Toronto, are so bad that the members cannot hear each other across the floor, and visitors in the gallery might as well be at a pantomime. Public opinion is divided as to whether the architect is a blunderer or an unconscious philanthropist. If all legislative chambers were arranged on like principles the members might give up talking, do nothing but work, and save both the ears and the purses of their countrymen.

THE LAND SURVEYORS' ASSOCIATION OF THE PROVINCE OF QUEBEC.

On the 10th of April was held the annual meeting of the above Association in the Government Buildings in Quebec. Matters of general interest were discussed by the 35 members present, and papers were read by Messrs. W. McLea Walbank on "Provincial Land Surveyors—What We Are and What We Will Have to Be," and by Mr. J. N. Castonguay on "Euclid as Applied to Surveying." At a meeting of the Board of Directors held the previous day, the following examiners were appointed for the ensuing year : Messrs. J. E. Mailhot, of Quebec ; B. C. Talbot, of Montmagny ; J. N. Castonguay, of Arthabaska ; D. C. Morency, of Levis, and W. McLea Walbank, of Montreal. The annual examinations were held immediately after the annual meeting and lasted until the 20th. There were seven candidates for admission to practice, of which one, Mr. J. E. Marion, passed. For admission to study the only candidate was Mr. Jerman, who passed successfully. The members of the Board of Directors, who are eligible for three years, are as follows : President, Messrs. A. Painchaud ; 1st Vice-Pres., W. McLea Walbank ; 2nd Vice-Pres., P. H. Dumais ; Secretary-Treasurer, C. E. Gauvin ; Syndic, George Roy, and Messrs. Thos. Breen, J. N. Castonguay, P. C. Talbot, J. E. Sirois, John Sullivan, D. C. Morency, J. P. B. Caspain, J. E. Mailhot, J. L. Michaud, F. X. Genest.

COUNCIL OF ART AND MANUFACTURES OF THE PROVINCE OF QUEBEC.

On Tuesday, the 30th inst., took place the official closing and distribution of prizes to the students of the evening classes of the Art and Manufactures School, with whose work the readers of the CANADIAN ARCHITECT AND BUILDER are already familiar, this institution having been the subject of my monthly correspondence in your November issue. The meeting was held in the Monument National on St. Lawrence street, in the same building as are now located the classes themselves, the accommodation at the old St. Gabriel street school having been found inadequate for the ever-increasing number of students.

There was a large and enthusiastic assemblage presided over by the President of the Council, Mr. L. J. Boivin, accompanied on the platform by the Vice-President, Mr. J. C. Wilson and Messrs. Hon. Judge Jette, Hon. Joseph Royal, Ex-Ald. Clendinneng, J. W. Hughes and others. The President opened the meeting by reading an address containing an historical sketch of the Council from its foundation up to the present date, accompanied by a most convincing proof of the great good conferred by the institution on apprentices in the several branches of the industries, and artist students, in giving them preliminary instruction in the great principles of art, and also treating of the greater good which must result in the future, to individuals, students and the country at large. The address was in substance as follows :

"Ladies and Gentlemen—I seize this opportunity afforded me by this distribution of prizes to the pupils of the night schools under the patronage of the Council of Arts, to say a few words as to the object the Government of this Province had in view in establishing that Council.

"On the 24th Dec., 1872, the act passed which legally constituted this Council to replace the old Board of Arts and Manufactures. The object of the Council, like that of the Board, its predecessor, is to advise the Commissioner of Agriculture and Civilization, and the Department of Public Instruction, as to all measures of a nature to develop the progress of Arts and Manufactures in this Province. Now that twenty-two years have elapsed since that period, when I recall to mind those who formed part of the first Council, it is impossible for me not to admire the wisdom which presided at the selection : the clergy, the liberal professions, journalism, trade and industry, were all represented.

"It is a generally admitted fact that the population of this Province have a natural talent and aptitude for handicraft, and especially for working in wood, iron and stone. There is probably not a single village which does not contain several youths who have a really remarkable talent for drawing. Unfortunately, this talent remains unknown and undeveloped through want of that technical education which we endeavor to give in our schools. It is very important that before learning a trade the workman should be able to trace on paper the model of what he wants to do, for drawing is the soul of all technical education. Once he knows how to draw he will easily understand and execut his work in wood or iron. If any article is made in accordance with the rules of drawing and geometry, it will not only be solid and useful, but will also have the elegance which will make it preferable to the purchaser. Take, for instance, the dress goods sold in our shops. Select two pieces of the same weight and quality ; there is no difference in the use for which both are intended. How is it, therefore, that one sells for 25 per cent. more than the other? The reason is very simple : the pattern or design of one is the work of a man who is educated in the art of his trade ; a workman who, during his apprenticeship, was not afraid to come and spend three evenings a week learning drawing, developing his intelligence and thereby securing for the future wages sometimes thrice as high as his companions, as intelligent and capable physically as himself—with this difference, however, that they neglected to learo while young. Examples might be multiplied indefinitely, but this one is sufficiently striking to convey my meaning.

"But, ladies and gentlemen, there is another and much higher consideration, which alone would suffice as a reason for the existence of these schools, and amply reward those who make sacrifices for their development. Man by nature loves and constantly seeks the beautiful. By developing this faculty he admires still more the handiwork of the Creator in all his surroundings. When he traces on paper a mountain, a river, a pure and cloudless sky, he sees everywhere the hand of the Great Master of all things. His soul rises higher and higher, his intelligence develops itself more rapidly, and the sense of beauty which he acquires will, without effort, inspire in him a sense of right. The workman, with the education suited to his trade, will not only always command better wages, but, from the fact of his intelligence being more fully developed, he will be a steadier workman. His cottage, however modest it may be, will be a model of cleanliness and taste. Thrift will reign in his home, because he will not have contracted bad habits in his youth, but it is in his great respect for the laws of his country that the State will reap its reward for the sacrifices it has made in educating the working man.

"Such, ladies and gentlemen, are some of the results which we have endeavored and are still endeavoring to obtain by further developing these working-man schools placed under our control. In looking over what has been done in twenty years, I was myself surprised at the great number of pupils who have been through our classes. I have made a summary of the attendance books of our various schools, and I find that, from 1872 to 1894, twenty-three thousand five hundred and seventy-five pupils have attended our classes. These classes are in Montreal, Quebec, Three Rivers, Sorel, Levis, St. Hyacinthe, St. Romuald, Sherbrooke, Huntingdon, St. Jerome, Granby, Chicoutimi, Farnham, Sillery, and for some years at Iberville. The Government of this Province has expended $185,200 in twenty-two years for the maintenance of these schools, say about $7.85 per pupil, making 35½c. per head per annum.

"I fancy I hear many of you asking of what use has this instruction been. What has become of the pupils who have passed through your schools during twenty-two years? The report of our Secretary for 1893 to the Honorable Commissioner of Agriculture, gives the answer to these questions. This report contains the names and occupations of 550 of our former pupils, who all fill important positions, either on their own account or as foremen in industrial establishments. Several of them are now in Paris or Rome continuing their studies. However, the number of those who owe their success to the instruction they have received in our schools is much larger, but you understand how difficult it is for us to discover their whereabouts. This, ladies and gentlemen, is what has been done in the past. The specimens of the work hanging on the walls show sufficiently what we are doing now.

The removal of our classes from premises which had become too small, to this splendid building, calls upon us to do much more than has been done in the past. New requirements demand our attention. To our classes in freehand, mechanical and architectural drawing, we will soon have to add classes of mechanical application. Pupils must be taught to apply to material substances the principles they have learned to put down on paper. Workshops with forges and turning lathes have become indispensable. Carriage-making, joiner-work, brick-making and laying, stone-cutting, making wooden patterns for iron and brass foundries, filing and polishing iron and wood, are so many things which want of means has hitherto prevented us from taking up. It is for you, gentlemen, who by your social position, are more especially charged with the duty of watching over the welfare of your fellow-citizens, to reflect upon the material and moral advantages that would flow from such a teaching.

And what have we done for the working-women. We frequently receive petitions asking us to do something for them. In our large towns there are those who are only waiting for the opportunity to acquire instruction in the various occupations which are suited to them. If we do not hasten to do something, the time is not far distant when they will work at many things which are now reserved for men. Most offices now employ women as stenographers, typewriters and assistant accountants. To my mind such a state of things is subversive of social order and can be productive of no good. Without doubt, women, at well as men, are subject to the law of labor, but we must carefully avoid whatever may contribute to lower woman's influence in the family. Let us give her cooking schools, where she can learn cooking, and study those industries which are specially suited to her sex—easier for her. Let them study needlework and crochet, which, with the aid of the study of drawing, might be made much more remunerative than any work they now do in shops, offices and factories. By developing the kind of instruction suited to working men and working women, we will escape those anomalies which threaten to subvert our social condition, to the detriment of the family, which is the basis of every well regulated society.

"Such, ladies and gentlemen, is a programme which is only slightly outlined, but which calls more and more for the attention of every citizen who wishes to promote the welfare of his fellow-citizens and of his country. In the first place, we must have those schools of application, of which I have just spoken, in which the great principles of mechanics would be applied, in which the future foremen of our large workshops would be trained, instead of our having to go abroad for them. I believe that before long our means will allow us to develop that portion of our programme. The installation of these workshops in schools are expensive, but fortunately there exists an establishment in Montreal with ample plant, which could be completed at a comparatively slight cost. I mean the institution founded by the executors of the late F. X Beaudry at the corner of St. Catherine and St. Urbain streets. Circumstances have not permitted these executors to give it the development which the testator had in view, but I have reason to believe that before long it will be again devoted to its object—the instruction of young workmen in the mechanical and industrial arts, and that an understanding will be arrived at between the Council and the administrators of that estate for the use of these workshops.

"We have everything needful for training our young men for the liberal professions ; we now have excellent commercial colleges, where those who wish to adopt business pursuits find everything necessary to prepare them for that important career ; but what have we for preparing those who are destined to industrial arts? Nothing, or almost nothing, and yet, gentlemen, the constant transformations of industry call continually for educated workmen to allow us to maintain an honorable position in this vast country. We must do here what is done in England, France and Germany : the municipalities must assist the Government. There are towns in England of from 3,000 to 4,000 souls, which allow these schools from $25,000 to $50,000 a year. How could the corporation of the city of Montreal more profitably employ a sum equal to our subsidy from the Government—$10,000 a year? With such an additional amount, the number of our pupils would soon reach 1,000 to 1,200. Montreal would become the great centre of industrial teaching for the whole country.

"The citizens who are always interested in seeing that their money is judiciously expended, should take an interest in the development of these studies to which they have hitherto been so indifferent. These, ladies and gentlemen, are the suggestions which I have thought proper to make on this occasion, where we have representatives of all classes of society assembled together. May these suggestions bear the fruit which I hope from them."

Then came speeches from Hon. Judge Jette and Hon. Jos. Royal, followed by a lecture on "Practical Education" by Mr. J. W. Hughes, which we regret, owing to pressure of space in this number, we are unable to publish.

The distribution of prizes, amounting to $145 in value, followed the speeches. The prizes were distributed in cash to the most deserving pupils of the different classes as follows :—

Freehand Drawing (Advanced)—Mr. E. Dyonnet, Teacher.—1st prize, S. Robertson, $10 ; 2nd prize, J. B. Lagace, $6 ; 3rd prize, N. Chaput, $4.

Freehand Drawing (Junior)—Messrs. E. Dyonnet and J. H. Egan, Teachers—1st prize, Jas. Gray, $8 ; 2nd prize, A. L. Dupont, $5 ; 2nd prize, B. Aubin, $5 ; 3rd prize, Geo. Moore, $4 ; 4th prize, W. Fleming, $3.

Architectural Drawing (Advanced)—Messrs. H. J. Peters and P. N. Picard, Teachers—1st prize, Charles Mitchell, $5 ; 2nd prize, A. Paquet, $4. Beginners—1st prize, E. Desautels, $5 ; 2nd prize, A. Caror., $3.

Mechanical Drawing, (First Season Pupils)—Messrs. J. T. Gardhan and Jos. Clement, Teachers—1st Prize, G. Wooley, $5 ; 2nd prize, F. Ponton, $3 ; 3rd prize, A. Reid, $2. Pupils of more than one season—1st prize, J. Boisclair, $5 ; 2nd prize, W. Pettigrew, $3 ; 3rd prize, J. Lacroix, $2.

Lithography—Mr. J. A. P. Labelle, Teacher—1st prize, H. Jackson, $4 ; 2nd prize, Jos. Gray, $3 ; 3rd prize, H. S. Nutter, $2.

Modelling—Mr. J. O. Gratton, Teacher—1st prize, E. Soucy, $4 ; 2nd prize, Louis Philion, $2 ; 3rd prize, A. Monastesse, $1.

Wood Carving—Same Teacher—1st prize, E. Laliberte, $3.

Plumbing (First Division)—Messrs. W. Britton and J. A. Peard, Teachers—1st prize, D. Coristine, $6 ; 2nd prize, H. Russell, $4 ; 3rd prize, Z. Bisson, $3 ; 4th prize, T. Daigle, $2. Second Division—1st prize, G. Guerin, $5 ; 2nd prize, J. Laroche, $3 ; 3rd prize, G. Jax, $2 ; 4th prize, A. Duclos, $1.

Stair Building and Building Construction—Mr. L. H. Blouin, Teacher—1st prize, J. B. Martineau, $5 ; 2nd prize, Jos. Laplante, $3 ; 3rd prize, H. Paquet, $2.

Prizes were also distributed to the Boot and Shoe Pattern Making Class, but are omitted, as they hardly interest our readers.

The exhibition of specimens of the pupils' work held from the 29th April to the 4th inst., on the occasion of the distribution of prizes, was located in the large Banqueting Hall of the Monument National, where each branch of the school established all through the Province, had a wall space and tables allotted to their exhibits. The first exhibit that met my eye as I entered was that of Levis, consisting mainly of mechanical drawings. These were accompanied by freehand drawings rendered in crayon, one of which, a floral study by Mr. Geo. Buckhand, is worthy of special mention. Mr. Jos. Turgeon exhibited a good drawing of the figure of a woman, as did also Mr. S. R. Page. If Quebec did not possess an extensive exhibit, it was nevertheless well represented by Mr. J. A. Gosselin with his drawing of a head of a child, and by Mr. A. Turcotte with his drawing of a typical old "habitant" of the French province, rendered in lead pencil, which, while not possessing all the brilliancy of the crayon, is none the less more pleasing

Montreal, as it might be supposed, had the most extensive exhibit : the advanced class of Freehand Drawing, the Modeling class, the Plumbing class, the Lithography class, all making a very good showing, but unfortunately half of the balance might as well have been left out altogether. The evident cause of the failure of the Architectural class is no doubt to be attributed to the fact that this class is mainly frequented by apprentices connected with the building trades, and who have had but one season's practice. The architectural student, having enough geometrical drawing practice during office hours, prefers to follow the course of the Modeling class or the Freehand Drawing class, where he is likely to derive more advantages. Mr. Charles Mitchell, a young architectural student, the winner of the first prize, exhibited drawings showing considerable skill, and his drawings in fact were the only exhibits of any interest in that section, one being a suburban residence in the colonial style rendered in water colors, and the other, two designs for school buildings, one of which was drawn in perspective in pen and ink.

In the Advanced Freehand Drawing class Mr. S. Robertson was without comparison the leader, all his drawings being nude studies of figures drawn in a sketchy way, and exhibiting a considerable knowledge of anatomy. Most of the other drawings exhibited were drawn from plaster casts executed by the pupils of the Modeling class of the school. Messrs. D. Coristine and H. Russell, of the Plumbing Class, have done work that could well compare with that of many excellent and experienced plumbers. The Modeling exhibit, although consisting of few specimens, was one of the finest in the Exhibition, and Mr. E. Sousy's work might fittingly find a place in the International Exhibition of Art.

Mr. A. C. Hutchison is daily expected to arrive home from his European tour.

I have been requested to state that Mr. Mann, the architect of the French Baptish church, corner of Cadieux and St. Catharines streets, which has been condemned and ordered to be torn down, is not Mr. Eric Mann, the well-known architect of St. John street. The latter gentleman, unfortunately, owing to similarity of name, has been getting credit in many quarters for the failure which this building has turned out to be.

STUDENTS' DEPARTMENT.

DOMES.

DOME is usually understood to mean a roof which is round or polygonal horizontally and of which any vertical section is either a round or a pointed arch. There happen to be none of elliptical or any other section than these. But some, especially in the East, have what is called an ogival outline, convex below and concave towards the top, and these are generally called cupolas, though there is no real distinction. Most of the great European domes have an opening or eye at the top, on which stands a lantern, except in the Pantheon at Rome, where the eye is open. Until modern times all the domes worth notice were of masonry—i. e., stone, brick, tiles, or pots, which last were used for lightness.

Pointed domes are much larger than hemispheres, having lost the flat top which has the greatest bursting pressure. A dome generally by the revolution of an equilateral arch, or one of sixty degrees, requires only a thickness of 0.137 diameter, 16½ in. for 100 ft., and one of seventy degrees requires 20 in. The tension at the bottom of a sixty-degree dome is only .15 of its weight, which weight, however, is 372 of a hemisphere on the same base, their heights being as 173 to 1.

For the same reason pointed domes are fitted for carrying a lantern, but they are not much benefited by tapering, having already lost the most oppressive parts. The Florence dome, across the flat sides of the polygon, is about seventy degrees of the circle of its curvature. Both in hemispherical and pointed domes the weight of the lantern they will carry varies practically as the cube of the thickness. Moreover, a lanterned dome requires tying much higher up than a plain one. In short, the cone is the only proper way of carrying a stone lantern. The cone at St. Paul's has a great chain round the base, which is probably superfluous, as the drum below it seems to be thick enough to contain the requisite slope, and visibly leans inwards besides.

Ribs inside a dome weaken more than strengthen it, as some persons imagine, unless they are themselves deep enough to be stable as independent arches, or unless they decrease in width and weight upwards like a lune, as those in the Pantheon do, which also is so enormously thick at the haunches that it has superabundant stability. Some of the Indian domes are thick enough for arches, and they have neither eyes nor lanterns. Polygonal domes may be considered as composed of a small number of widish lunes, and only differ from round ones in being rather weaker for any given thickness and size.

Domes require no wooden centering to build them on as arches do, until they get near the top—i. e., so long as each stone is laid on the ring of stones below it will not slide inwards. And if they are notched to prevent sliding the whole dome may be built without centering. The dome of Mousta in Malta was so built in this century by a common mason, who must, however, have been a man of genius. There would be no difficulty in building a dome of almost any size of bricks or stones, with the help of hoop iron in all the lower courses up to about twenty-three degrees from the bottom, and then less up to fifty-two degrees, and higher if it has to carry a lantern.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

MEMBERS and students of the above Association are invited to compete for a design for a seal, envelope and letter heading, to be delivered to the Secretary, 97 St. James Street, Montreal, before the 1st of August next. The design must be made so that the seal may be omitted or used as desired. The author of the best design will be awarded a prize of $10, the best four designs to be published in the CANADIAN ARCHITECT AND BUILDER.

USEFUL HINTS

There is an advantage in varnishing those parts of inside blinds which face the light, with good spar varnish. The exposure to weather and to the rays of the sun to which the facings of the blinds are subjected when closed, soon bleaches or blisters the ordinary furniture varnish that is commonly used on interior work. The exterior varnish being a slow dryer, withstands the elements much better than the varnish commonly used on interiors.

GLASS THAT EXCLUDES HEAT.—The announcement made of a German method of producing glass which will transmit light freely, but not heat, is supplemented by some details as to the process of manufacture. A plate of this material 4-10ths of an inch thick, containing 28 per cent. of iron in the form described as ferrous chloride, allowed only 4.06 per cent. of radiant heat to pass through it, while another plate of equal thickness, and and containing quite as much iron in the form of ferric chloride, permitted 11 2 per cent. to pass. The chemical distinction is very small, but the effect is said to be marked. A new thin slab of this glass permitted less than one per cent. of the heat of gas flames to pass, although transmitting 12 per cent. of heat from sunlight. Ordinary window glass, on the other hand, lets some 86 per cent. of heat through.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 6. JUNE, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, -- TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

THE movement for a Dominion organization of Canadian Master Plumbers is still being pushed forward, the Montreal and Ottawa local associations being the prime movers. The plumbers throughout Ontario and the maritime provinces have been invited to consider the question, and an effort will be made to hold a preliminary meeting for organization in the near future. The Montreal association at least appear to be desirous that the proposed Canadian Association should affiliate with the National Plumbers' Association of the United States. To what extent this feeling is shared by the local associations in Toronto, St. John, and elsewhere, has not been learned.

REFERRING to the article on another page concerning tests of fire-proofing material made recently at Deseronto, somewhat similar tests took place recently in Boston of several kinds of wood which had been rendered fire-proof by the injection of fire-proofing compounds. The process consists of forcing by hydraulic pressure a chemical solution into the substance of the wood or other material. A structure built of wood thus chemically prepared was blackened and carbonized to a depth of one-half or three-quarters of an inch, but otherwise remained unimpaired under the action of heat so intense as to melt the window glass. There appears to be no doubt that wood thus prepared will resist the action of fire, but the fact that its preparation costs from twenty-five to thirty dollars per thousand feet, is sufficient to prevent the process from coming largely into use. Porous terra cotta, on the other hand, is not only equally capable of resisting fire, but is likewise very moderate in cost, and has other properties which commend its use in building construction even where it is not required as a fire-proof material.

THE collapse of several large buildings in New York city recently, resulting in the killing of a number of persons, has drawn public attention to the necessity for the proper education of architects. In the case of one of the buildings referred to, a tenement house on Orchard street, the jury found the owner, the contractor and the building inspector to be criminally negligent in having used and allowed inferior material and workmanship. The plans also were found to be seriously defective, brick piers in the basement being loaded to the extent of ninety tons to the square foot, while the limit allowed by law was but eight tons to the foot. The architect of the building was practically unknown in the profession. The jury who investigated the circumstances in connection with the collapse of the building close their report as follows: "The most efficient check which could be placed upon practices of the kind which have led to this disaster, would be the licensing of all architects, who should be required to undergo a thorough examination as to their qualifications to practise an art upon which the lives of so many people depend." Legislation of this character the Ontario Association of Architects have been endeavoring for several years past to have placed on the statute books of the Province of Ontario, and it is to be hoped that their petition will be granted before disasters similar to those which have occurred in New York shall be witnessed in this country.

IN reply to a letter from Mr. Jas. Robertson, of Montreal, concerning the use of galvanized pipe for conducting water into buildings for drinking and culinary purposes, Prof. J. T. Ronald, of Bishop's College, writes as follows: "Certainly it is unwise to use such pipes for the distribution of water for domestic use; some waters would in all probability have very little effect on the zinc, others again might dissolve notable quantities of this metal, and all compounds of zinc which are soluble are poisonous. It therefore follows that in some cases no trouble would arise from the use of galvanized pipe, whilst in other cases such pipe might be the means of introducing into the water a larger or smaller quantity of a corrosive zinc compound. It would be safer not to use such pipe."

THE second appeal of Mr. Neelon, the contractor for the Toronto City buildings, from the decision of the lower courts, refusing him an injunction to restrain Mr. Lennox, the architect of the building, from interfering with or preventing him from carrying on the work on the building under his contract with the corporation, and to compel the defendants to deliver up possession of the works and for other relief, has been dismissed by the Court of Appeal, with costs against the plaintiff. The ground on which the trial judge refused the petition of the plaintiff was that under the contract the architect had power to dismiss the plaintiff without the consent of the court house committee of the City Council. It has not been learned whether it is the intention of the plaintiff to carry the appeal further.

A REAL estate boom similar to the one experienced by Toronto a few years ago, appears to be setting in at Buffalo, and speculation in land and building in that city, is at present unusually brisk. Several Toronto real estate men are said to be operating at Buffalo, neglectful of the experience which many of their class received in Toronto so recently. As mentioned elsewhere, a number of Canadian contractors have also gone to Buffalo in view of the extensive building operations which are in progress in that city this year. It is believed that the Buffalo boom is on a somewhat more solid foundation than the one through which Toronto passed. The location of the city is such that it is believed to be certain to become one of the greatest commercial and manufacturing centers of the Uniten States.

In our Montreal correspondence we print a petition which has recently been presented to the City Council of Montreal, by the Council of the Province of Quebec Association of Architects, asking that a committee be appointed to supervise the erection of public monuments, the laying out of parks, etc, in that city. We are pleased to see this action taken, and trust that the example of the Province of Quebec Association will be followed by the Ontario Association of Architects, so that if possible the appointment of committees of this character may be secured in the leading Canadian cities. The need of some properly qualified authority to govern the erection of public monuments is apparent in Toronto at the present time. Had such a committee been in existence, the Volunteer Monument now in the course of erection in Queen's Park would probably have occupied a different site. The proper place for monuments of this character would be in the rear of the Parliament buildings. The space in front of the buildings should be reserved for statues, and the mixing up of statues and public monuments of the character of the one mentioned should not be permitted.

No understanding has yet been arrived at between the Builders' Exchange, representing the master builders of Toronto, and the bricklayers' and stone masons' unions, for the renewal of an agreement to govern the rate of wages to be paid the workmen in these trades. The only union with which an understanding has been reached is that of the labourers. The other trades are apparently not satisfied to accept the reduction of about 20 per cent. agreed to by the labourers' union, and we feel quite safe in saying that these are the best terms which they will be able to make. In an article elsewhere in this paper, the fact is mentioned that contracts are being taken to-day at one-half the figures obtained twenty years ago, and that never before in the history of Canada were prices so low as at present. Under these circumstances it is folly in the extreme for the trades unions to demand or expect to be paid the same rate of wages as they have been accustomed to receive hitherto. We are informed that owing to the refusal of the unions to moderate their demands, a number of their members are deserting their ranks and are making their own terms with the employers, whilst others are being expelled owing to their inability to pay their dues. From these two causes the strength of the unions is being sapped, and they have everything to gain by endeavoring to come to an early understanding with the employers.

THE information comes from London that electric radiators have been successfully employed as a means of temporarily heating the Vaudeville theatre in that city, and that in consequence electric heating is likely to come into use in a number of public buildings in that city. The advantages of the electric system are that radiators can be placed in out of the way corners which would be difficult to heat by steam pipes, and that they can be stored away when not required for use. While the system is undoubtedly more expensive than steam while in operation, yet less than half the time is required to bring the temperature of a public building up to the required standard of comfort than when steam is used: thus the extra cost while in operation in offset by the shorter time in which it performs its work. Another advantage is, that the temperature can be perfectly regulated to suit the requirements, and the employment of skilled attendants is to a large extent avoided. The question as to what heating methods will be employed in the future is an interesting one. One thing is absolutely certain, viz., that the use of coal as a means of generating heat is not likely to be continued much longer. The manner in which gas is superseding coal for cooking purposes shows clearly the trend of public opinion. The coal stove is being banished from the kitchen, and it is safe to say that the coal furnace will soon follow.

WHILE a fair amount of building is being done throughout Canada this season, contracts are being taken at figures lower than ever before, and consequently there is little profit in the work. A warehouse building which was destroyed in the recent Toronto fires is being rebuilt at exactly one-half its original cost. In other words, a building which twenty-one years ago cost $12,000, is now being put up for $6,000. At the time it was originally built, the brickwork cost $15.00 per thousand, as against $11.00 per thousand to-day. Prices of material have also gone down, but it cannot be said that the cost of manufacture, in the case of brick, for instance, has been reduced in like proportion. It is true that by means of improved machinery the cost of making brick has been considerably reduced, but on the other hand the cost of burning has increased by about $1.00 per thousand as the result of the increased cost of fuel. Apparently, the keenness of competition has served to reduce tenders in other cities as well as Toronto. As an illustration of this, the contract for one of the new churches to be erected in London, is said to have been let at about $10,000 below the architect's estimate. The majority of contractors have been so long without employment that now an improvement has set in, they are willing to tender at ridiculuously low figures in the hope of securing work. The result of such a state of affairs is by no means satisfactory. It tends towards inferior work both on the part of the contractor and the architect, as the latter is affected by low prices in the same way as the former. Cheap work by contractors means additional worry for the architect and reduced commissions. We learn that quite a number of contractors have recently gone to Buffalo and other American cities where building operations are brisk, and this will no doubt tend in some measure to improve the condition of things in this country.

News comes from New Brunswick that the St. George Red Granite Works have ceased operations because of the refusal of the employees to accept a decrease in wages, demanded of them because of the competition of Scotch granite in Western Canada.

Mr. Charles T. Cote, inspector of factories for the City of Quebec, and Mr. Joseph Lessard, inspector of factories for the Montreal district, have been appointed inspectors of religious institutions for their districts, to enforce the new Provincial laws respecting the safety of those buildings.

SURVEY OF THE BUILDING SEASON.

Is work looking up? This is a question asked by most men engaged in the building trades, and with midsummer well nigh reached, it ought to be possible to provide an intelligent answer. In Toronto, as an outcome of the great fires the early part of the year, a number of large buildings are under construction. Permits have been issued for the erection of the new store for R. Simpson, the Globe office, McKinnon's wholesale warehouse, Rooney & Co.'s warehouse and several other structures in the business districts of the city. The new Foresters' building is also a work of some magnitude, and it is being pushed forward with energy. These taken altogether will run the permits of 1895 into large figures. This work, however, acceptable as it is, is yet abnormal, and cannot be taken as representing a genuine revival in the building trades. Go outside of these contracts and the figures in Toronto will not total up very large. Few contracts have been let for house building. Drawings are completed for a number of private residences, and in some cases permits have been issued and the work commenced, but these are not sufficiently numerous to cut a large figure in any estimate of the building operations of the season. Briefly stated, it has to be admitted that the depression in the building trades that has been a feature for several years, since the days of the breaking of the real estate boom, still continues.

Some factors that enter into building operations, if not new, are deserving of consideration. The recklessness that characterizes tendering for work this year is fully as manifest as in some of the worst years of the recent past. A study of the tenders that come in for almost any class of work, whether on a small scale, or some of the more extensive operations, is full of interest. On a contract running into a few thousand dollars, there will be sufficient difference between the highest and lowest tenders to indicate that good judgment, much less business commonsense, has had little to do in the calculations. This is a condition that reacts upon everyone associated with building operations. The man who contracts to do a job at 25 per cent. less than a profitable price must even up somewhere, or else the time will speedily come when he will count out, and creditors will suffer. As it is, building supply men have prices forced down to a figure that means no profit to them, and necessarily, wages must come down with other values. The architect suffers, for with every decrease in the estimated cost of building, his percentage experiences a decline. Of course, the argument is that if one man does not tender low, his neighbor will do so, and get the job. This explanation does not remedy the evil, and emphasizes the great need there is for men engaged in the building trades arriving at something like a sensible policy in placing tenders.

There is a lot of nonsense talked about the benefits that come to the masses when low values prevail. A study of economic laws and the lesson of careful observation is, that business thrives when prices are reasonably high, and it is when values have the life squeezed out of them, so to speak, that every individual in the commonwealth is a sufferer. Wheat at 50c a bushel may seem to mean cheap flour for the masses, but the past year's history of wheat in Canada runs parallel with a season of depression in which all classes have suffered. With this important article of consumption now doubled in value word comes that business is on the turn, values hardening in all important lines, wages being advanced, and good times returning. This hardening of values, that is reported in iron, steel, hides, wheat, and other products, unfortunately, does not find any immediate placement in the building trades of Canada, though there is reason to believe, that in the near future, conditions will change here, as they are changing in the country to the south of us.

Prices for building material have seldom been more depressed than this season. To quote the words of a leading Toronto architect: "Bricks can be bought almost at one's own price, stone is simply not in the calculation, so demoralized is trade in this line, Portland cements are certainly away down, sewer pipe is cheap enough to suit anyone, lumber is showing some tendency to advance, though current prices here have not changed much, iron and steel, being the only supplies that enter into building construction where prices are hardening."

The conditions that prevail in Toronto are in the main illustrative of the situation generally throughout the province, and other parts of the Dominion. London has been helped, as Toronto, by fire, and two leading churches, that were destroyed this year, are being replaced by new and handsome structures. With this exception, there is no building boom in the Forest City. Steady progress is being made in building lines in Hamilton, and the people of that city are satisfied with this growth, but no great things are to be reported from there. And so one might run through the leading cities and larger towns throughout the Dominion.

Building in Toronto will be helped later when the demand for habitable houses more nearly reaches the supply, and with a revival in general business, this day will not be very long postponed. In country towns and rural districts building this season is fully up to, and probably, ahead of late years, many important buildings in the line of school houses, and other public institutions being in course of erection. Taking the Dominion over the season will, on the whole, maintain the average of recent years, with the outlook for the future improving.

WATER HAMMER IN STEAM PIPES.

Recently numerous explosions of high-pressure steam pipes led a German engineer to call special attention to the great danger from water hammer. To prove this experiments were undertaken to show the high pressure in a pipe when water hammer occurs. A pipe 12 inches in diameter, ¼-inch thick and 21 feet long, blank-flanged at one end, was partially filled with water, and at the other end steam supplied through a three-inch pipe. Three pressure gauges at equal distances were screwed to the pipe and one in the black flange. When steam of five atmospheres, 73 pounds per square inch, was admitted suddenly above the water, the pressure gauges indicated respectively pressures of 426 pounds, 114 pounds, 199 pounds and 114 pounds per square inch, or nearly 30, 8, 14 and 8 atmospheres. When steam entered slowly again above the water, hardly any concussions and abnormal pressures were noticed. Steam was then admitted through a valve 2 inches in diameter, and the steam, at a pressure of 5 atmospheres, now entered below the water. The concussion was so violent that the threads of four of the nuts were shorn off, the fourth gauge placed there was crushed, though the gauges were designed for a maximum pressure of 2,133 pounds per square inch, while the other gauges indicated pressures of 483, 385 and 923 pounds per square inch. The end of the pipe bulged considerably. On a new trial the first three gauges registered 313 pounds, 185 pounds and 853 pounds per square inch, the fourth, refitted, over 2,130 pounds; a rent of eight inches in length formed, starting about four inches from the far end. This damaged part was then cut off, the pipe closed again, and the water level lowered to 63¾ inches; pressures of 498 pounds, 498 pounds and 853 pounds per square inch were then observed. The water level was then raised to 10 inches and steam turned on again; this time two bolts broke in the end plate, and fissures formed near the middle of the pipe. In all cases air and water were thrown out through the air and water outlets. This occurred always in sudden rushes, after an interval of 15 seconds, when steam was turned on fully, and of several up to four minutes, when the valve was only partially opened, to one-fifth in the last instance. Only part of the water was forced out; a minimum of 3 inches always remained in the pipe. The experiments prove that the blow did not begin before the steam had condensed and the water had acquired the respective temperature. The different indications of the gauges seem to show that the blow was propagated in waves, which affected the pressure gauges according to their positions. The maximum pressure observed was 30 times higher than that of the steam which caused the concussion. If we consider that the steam inlet had only one-thirtieth of the area of the steam pipe, that steam pressures of three times the intensity of those experimented with are actually used on shipboard, and that part of a pipe might, under circumstances, be entirely filled with water, we must admit that these lodgments of water may lead to most disastrous consequences.—Engineer and Iron Trades Advertiser.

The corner stone of a new Catholic church at Cobourg, Ont., was laid on the 9th inst.

The Standard Drain Pipe Company, of St Johns, Que., have elected the following officers: President, W. C. Trotter; Vice-President, Capt. Chas. Coursol; Directors, G. H. Balfour, T. H. Dunn, F. C. Henshaw, and J. T. Ross.

PROPOSED PALACE HOTEL FOR TORONTO.

THE project, considerably talked of in recent years, to build a hotel on a palatial scale in Toronto, seems likely to develop, shortly, into a reality. A fortnight ago, Mr. James Rothschild, of New York, a large capitalist and owner of the new Majestic hotel in that city, visited Toronto, for the purpose of considering the advisability of building a hotel on a similar plan here. He is reported to have been well pleased with the outlook and intimated his willingness to put $400,000 into the project, providing certain local conditions are complied with.

Mr. G. W. Yarker, the well-known banker, is representing local interests in the project. A representative of the CANADIAN ARCHITECT AND BUILDER had an interview with this gentleman some days ago. Whilst not prepared to say that the project is an absolute certainty, he intimated that everything was developing favorably, and that it was likely to take practical shape at an early date. Mr. Rothschild had gone carefully into the matter, studying the local situation, and was satisfied that the investment would prove a profitable one. The Ontario government has given Mr. Yarker the necessary assurance that the site, which has been selected, namely, the old Upper Canada College grounds, could be secured on conditions agreeable to Mr. Rothschild. It is expected that $200,000 of local capital would be subscribed, and that the city will grant certain privileges in the way of a favorable rate of taxation and low water rates.

The proposed building will be modelled after the Majestic, of New York. It is a twelve storey building, with six hundred rooms and two hundred and forty-five bath rooms. The Toronto hotel would be eight stories high, though covering a wider area of ground, with three hundred rooms and nearly two hundred bath rooms. In many respects, the Majestic is planned on new and attractive lines. The rooms on each floor are arranged in suits, as well as single rooms. The idea is to cultivate, especially in the winter season, a family clientage. According to the plan proposed, a family may have its own suit of rooms, which will either be furnished by the hotel, or the guests themselves, and these are so arranged, as will be seen from an illustration of one floor of the Majestic, issued with this number of the ARCHITECT AND BUILDER, so that the utmost privacy and home-like features are secured, even to the private hall.

In Continental cities, particularly in France, it has become the custom with many of the better class of families to reside at hotels conducted on the plan of the Majestic, rather than keep house. And this custom has been taking a good foothold lately in United States cities, as is witnessed by the success of that now famous hostlery, the Waldorf, in New York, built by the Astors, and the large share of business that has come to its latest rival, the Majestic, since its opening in October, 1894. What may be the result of any extensive change in the domestic life of Toronto, and its possible bearings on residental property, is, perhaps, a question that would come into consideration here. Mr. Yarker believes that the business the proposed hotel would gather around it would be very largely of its own creation and not interfere, to any material extent, with existing conditions. He said that the projectors would not look for business that would, at the present time, be going to other hotels, though he had to admit, that naturally, what might be termed the better class of guests would prefer a hotel such as that now under consideration, were it placed at their disposal.

The expectation is, that the new hotel would draw to Toronto tourists who to-day pass it by. With other citizens, Mr. Yarker believes, there are few more attractive summer resorts than Toronto. "If," said he, "American families in large numbers will spend a month or more at a time at the Arlington at Cobourg, might we not expect a very marked influx of this kind of business to Toronto, with a hotel here built like the Majestic of New York."

The appointments of the proposed hotel throughout would be very attractive. There would be a banqueting hall on a scale of considerable magnificence and equal to every likely requirement of the largest conventions and public gatherings. A winter garden is a novel and beautiful feature of the Majestic, and this idea would be carried out in the new hotel. A garden in the courts and on the roof of the hotel would be another novelty. Here guests and their friends are supposed, when so inclined, to spend the evening and sit and sip at ice and enjoy the cool breezes of the lake, as in New York they do those of the Hudson or Central Park.

In answer to the enquiry, when it might be expected the new hotel would be completed, Mr. Yarker said it was hoped that arrangements would reach a point to permit of it being in readiness to receive the guests of the British Association for the Advancement of Science, which is to convene in Toronto in 1897. This would mean that arrangements would be well developed by the fall, so that plans could be prepared and building operations commenced in the early spring of 1896, if not before.

Mr. Yarker intimated that the drawings would probably be prepared by an American architect, and the work of construction placed under the superintendence of some well-known member of the profession in Canada. With an American capitalist largely interested in the project, and the new hotel to be modelled after an existing hostlery in New York, it is not unnatural that the employment of an American architect should be suggested. But there is another side to this matter. The proposed hotel is to be erected in a Canadian city. Substantial assistance is to be given by the provincial government, and favors are expected of the City Council, besides which not less than $200,000 of Canadian capital is likely to be subscribed. The work performed by Canadian architects is evidence that they are equal to the designing of such a building as that proposed; this being the case and all other things being equal, they should have the preference, and certainly an opportunity to prepare designs, if so desired. Another important consideration that should weigh in giving preference to Canadian architects, is the recommendations that are made as to the character of material that shall be used in the construction of the building. Canadian interests were prejudiced when an American architect was chosen to prepare designs for the Parliament buildings of the province. Within our own country will be found the men and the material, with few exceptions, to meet every requirement that will be called for in the proposed hotel project. We would not want to take narrow ground in this matter, but knowing what has been done in the past by Canadians, and the high position they hold in the architectural profession, what is asked is only fair and equitable.

CARLETON PLACE TOWN HALL COMPETITION.

Concerning the above competition, a correspondent writes the ARCHITECT AND BUILDER as follows:—"An article stating that the tenders for the proposed new town hall and fire hall at Carleton Place all proved too high, that new tenders will likely be called for, has been going the rounds of the technical journals for the last two months or more. It has occurred to me that a statement of what has actually been done would be interesting to you and to the architects who sent in plans in competitions.

"In May 1894 an advertisement appeared in the CONTRACT RECORD calling for plans for a "town hall and engine house", apply to the town Clerk for particulars. Those who applied were told they wanted a building of a certain size and kind, to cost from $15,000 to $18,000. In all fourteen plans were received. The Council accepted G. W. King's plan with an estimate of $19,500, and when tenders were called for, the lowest one was $23,700. All tenders were rejected, as were also the plans. The Council then instructed Mr. King to prepare new plans on the lines of the former ones, but to cost not more than $18,000. These plans were received about a month ago, the estimate of cost being $18,000. At a meeting of the Council held a few days later the Council, in committee of the whole, rejected the plans. At a special meeting held about ten days later they acted as stated in the enclosed clipping.

"I would like the other twelve men who sent in plans to know the treatment they got at the hands of the Council."

The clipping enclosed in our correspondent's letter contains a report of a meeting of the Town Council of Carleton Place to consider the Town Hall project, at which the following resolution was adopted:—

"Moved by Councillor McNie, seconded by Deputy-Reeve Moffat, that the clerk be, and is hereby authorized to return the sketch plans and specifications now before the Council to the architect, Geo. W. King, Toronto, instructing him to prepare the finished plans and specifications, which this Council will accept for tenders, as per agreement with architect, after the architect has made the following changes in the sketch plans and specifications: The external walls of building to be of stone throughout, and to be built three feet higher than called for on plans; these walls to be built below high water mark with large dimension stones full thickness of wall laid in cement. The main hall to have an elevated floor. The interior finish of ground floor hall, main hall and staircase, first floor, Mayor's room, committee room and clerk's office to be of black ash, instead of pine, as specified. And that the architect be asked to have these finished plans in the hands of the Council as soon as possible, so that tenders may be called for without much more delay."

ARTS AND CRAFTS ASSOCIATION.

As promised in your last issue I now give a more detailed review of this interesting association's exhibition.

To commence with, the architectural drawings, which are few in number when compared with those of last year, A. W. Penne had a good pen perspective of the Stinson street school; J. Walker had also a good perspective of a portico; A. W. Patterson showed eight different treatments of a street front.

The crafts exhibit was an improvement on last year's work. Gilson Bros., of McKenzie's Stained Glass Works, had six specimens of stained glass, all good in design and color. A bedroom suite in brid's-eye maple, designed by J. Burton, carved by A. Burton, and cabinet work by W. D. Taylor, employees of Hoodless & Son, was well worthy of close inspection. S. Boggs, employed by Malcolm & Soutes, had two daintily upholstered chairs. Chadwick Bros. had several specimens of spun brass work, which in point of finish and artistic turning, would compare favorably with the best work from Birmingham. A. Venator had a spool holder made of different woods glued up and then turned. A photo cabinet by J. Jeffrey is a first-class bit of cabinet work, carved, veneered and inlaid. L. Bailey exhibited a pair of brass dragon candle-sticks, very quaint in design. W. Ennis exhibited a piano made epecially for this exhibition, the style and tone of which is good. P. L. Scriven gives examples of wood engraving.

The artistic needlework forms a good exhibit—no doubt from the fact that Mrs. Wright, late superintendent of the Royal School of Art Needlework, London, England, has a class in the Hamilton Art School. The sofa cushion by Mabel S. Ireland is very rich in color. Kate Saunders has a chair, silk embroidery on white velvet, which for excellence of work takes us back to the 16th century. Mrs. Wright had several specimens of her work: most exquisite.

The loan exhibit of M. W. Devine, who has resided in India for 23 years, and during which time he has made a collection, is superb. Many a "pointer" has been obtained by Hamilton craftsmen from this collection. A. S. Wood and W. Marshall also contributed largely, both in the pictorial and crafts sections. Some designs for cotton prints by M. Sheed and M. Jackson are quite dainty, and show the outcome of the practical work of Hamilton Art School.

Among the local picture exhibits, those of Miss Knott were noticed. Her fruit pieces showed good handling. Mrs. Ireland had a triplet of sketches, in one frame, full of light and having a touch of nature in them. Miss Nellie Weylie had two subjects, one in oil, "My Kitchen Table," and one in water color, "Harmony," with the secondaries. The latter is a triple compositionof green mignonette, orange marigolds and purple cinerarias. Miss Baine, the Secretary of the Association, has five water colors of local bits. We expect to see in the near future some strong, telling work by this artist. Miss Ottelee Palin, too, has some carnations which bespeak excellent work at no distant date. Mr. S. J. Ireland, President of this Association and Principal of the Art School, has three oil pictures and five water colors—all painted from nature and not retouched in the studio, consequently very faithful bits of landscape.

To make art handicraft better understood and appreciated, while the Exhibition was on, the following crafts were particularly demonstrated: Stained glass, pottery, lithography, engraving, metal-spinning, wood-turning, wood-carving, etc. The exhibitors of these different crafts each gave one evening to practical work. Lathes and other heavy tools were brought in, and when power was required a 2 H. P. Kay electric motor supplied it. About 5,000 people visited the Exhibition and some sales were made.

In your last issue I inadvertently confused the Arts and Crafts Association with the Hamilton Art School. They are distinct societies, the former having come into existence through the latter training young students to take a place with practical workers. A small error like this is perhaps excusable, as Mr. S. J. Ireland, Principal of the Art School, is also President of the Arts and Crafts Association.

CORRESPONDENCE.

[Letters are invited to this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

ESCAPE IN CASE OF FIRE.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The destruction by fire of the McDonald factory, Montreal, with the loss of several lives, is another example of the absolute sinfulness, both of the proprietors themselves for not providing for escape, and of the government in not forcing them to comply with the provisions of the law relating thereto.

What mockery to tell us of the central tower for the escape of inmates, when, as proven in this case, for the hundredth time, this very tower, as with any elevator shaft or stairway communicating by doors from each floor or storey with the interior, is the immediate cause, if it be built of wood, of spreading the fire throughout the building, or at any rate of causing the smoke and asphyxiating gases simultaneously to invade the entire edifice.

How can it be necessary to repeat again and again—how can it not be seen or understood that any tower or stairway of the kind, or elevator, must have absolutely no communication whatever with the interior of the building? For, that even if it is incombustible or fire-proof, as must be an iron staircase surrounded by a brick wall, still can it offer no chance of escape, since it must and always does act as the flue of a chimney or ventilator shaft, by giving access to the smoke and heated air, thereby stifling anyone attempting to escape thereby.

No! the escape stairway must have absolutely no communication with the interior, but, as shown by the writer in a paper read by him before the Royal Society at Ottawa in 1888, and again before the Province of Quebec Association of Architects at Montreal in 1892, and in an illustrated article published in the CANADIAN ARCHITECT AND BUILDER for December of that year, (page 122), the inmates should be able to pass out simultaneously and instantaneously by the windows on to iron galleries or balconies running along each storey of the building and opening on to the stairway; so that, there being no direct communication between the building and the escape way, no draft can take place therein capable of sucking up the smoke and heated gases from a lower level.

In the case of a manufactory like McDonald's, where none but able-bodied persons are employed, iron ladders well out from the wall, to give a good foothold, and facing on a lane or courtyard, with iron balconies to reach them from every floor, through a window on each side thereof; (and these balconies need not be continuous where large apartments allow of the inmates flocking to the escape windows at some one point thereof) I say such ladders and balconies may amply suffice, and I am glad to say that Montreal already has many such humanitarian contrivances, as anyone can see by visiting the lane-way in rear of the St. Lawrence Hall, or between St. James and Craig sreets, and elsewhere; and it is pleasing to me here to chronicle to the world the existence of such careful forethought.

Why then was the McDonald factory without these balconies and stairs or ladders, if compulsory by law to have them, and if not compulsory, why not immediately make it so?

My recurring again to this matter of the McDonald fire, is forced on me from seeing it asserted in the finding of the jury or by some of the witnesses that "had there been no panic there would have been no loss of life."

Precisely so, but neither would there have been a panic, nor would there ever be a panic in any case, where means of escape were provided and made known in advance to the inmates, who should moreover be once in a while practised at using them, as in case of fire they would have to do.

I wrote the Montreal Star at the time of the McDonald fatality somewhat in the same strain, and it is to be regretted that a paper of such circulation should have allowed its readers to remain in ignorance of the true nature of a reliable fire-escape for fear of hurting Mr. McDonald's feelings or of jeopardizing his case before the jury of inquiry.

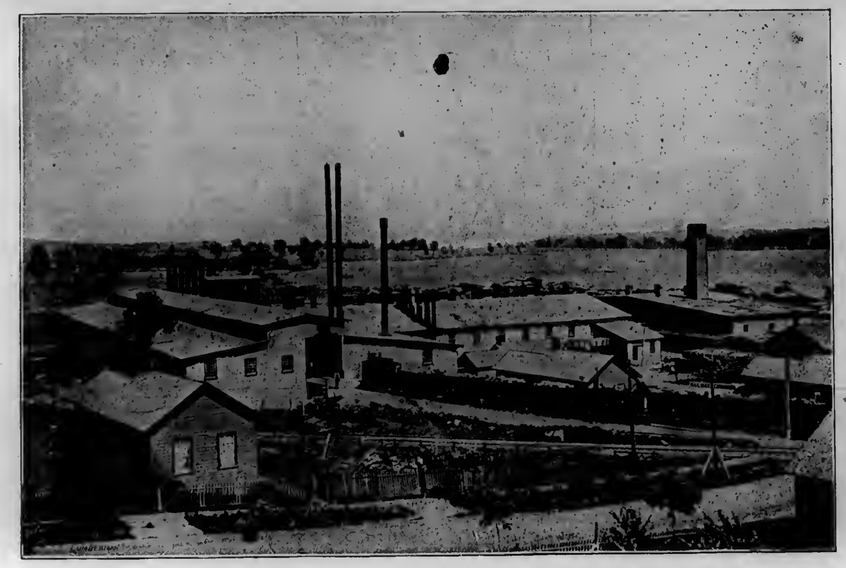
CHAS. BAILLARGÉ,
Architect, Engineer, Etc.

QUEBEC, June 10th, 1895.

TESTS OF FIRE-PROOFING MATERIAL.

By invitation of The Rathbun Company, a number of architects, principally from Toronto, paid a visit on May 23rd to Deseronto, for the purpose of witnessing a series of tests of porous terra-cotta fire-proofing material, manufactured at the Rathbun works. In addition to witnessing these tests the visitors were invited to inspect the various departments of the Company's extensive business, but a single day was found to be insufficient for this purpose. The inspection was therefore confined to the wood-working shops, the terra-cotta and brick manufactory, and the Portland cement manufactory at Napanee Mills.

The wood-working factory was first visited, and awakened a great deal of interest. The principal product of this factory is sashes and doors, in addition to all kinds of interior finish. An extensive and growing export business is being done. It is noteworthy that the doors manufactured to meet the requirements of the English market are much inferior in workmanship and material to those manufactured for the home market. It is thus possible for the manufacturers to utilize to advantage in their foreign trade, material which would not be acceptable for the home market. The factory is equipped with the latest labor-saving machinery, and every device that would reduce the cost of production appears to have been utilized. On this point the remark of an architect may be mentioned, that labor-saving machinery is not only an important agent in reducing the cost of building, but also in curtailing architects' commissions. It was noticeable that notwithstanding the variety of work being turned out, there was only one piece of work which was being manufactured by hand. This one exception consisted of a stair-rail of special design, which, of course, could not be made by machinery. In process of manufacture were some interior fittings for the Congregational Church at St. John's, Newfoundland. The interior of the factory was entirely free from dust, notwithstanding the large number of machines in operation. The dust from these machines is collected by fans and conveyed to the boiler room, where it is utilized as fuel.



THE RATHBUN BRICK AND TERRA COTTA WORKS, DESERONTO, ONT.

The terra-cotta works, which were to be the scene of the tests, were next visited under the direction of Mr. Rathbun, Jr., Mr. M. J. Hynes, superintendent of the works, and Mr. M. J. Butler, the company's engineer. The building is 390 feet in length, with a wing 190 feet long, and contains 200,000 feet of drying floor surface. The products of this manufactory are porous terra-cotta for fire-proofing purposes, terra-cotta for ornamental purposes, and dry pressed brick. The clay from which the porous terra-cotta is made is mixed with an equal part of saw-dust, the two materials being thoroughly ground together and afterwards passed down into the press. From one end of this machine is turned out porous terra-cotta arches, and from the other porous terra-cotta lining brick. The latter is dried quickly by means of a hot blast, while the former is elevated to the upper floors and air-dried to prevent cracking. This drying takes place in a temperature of 80 degrees, the temperature being maintained by the air passing over steam coils in the lower part of the building. Upwards of a mile of steam piping is in use for this purpose. The drying process occupies from ten days to two weeks. From these drying floors the material goes to the kilns to be burned. In the kilns the saw-dust is burned out, leaving the remaining material porous and very light in weight. The combined capacity of the several kilns is 300,000 pieces. These kilns are constructed on the down-draft principle, and are fed from a number of small openings in the top. It is a rather remarkable fact that one of these kilns, constructed of common white brick, has stood unimpaired for nine years the tremendous heat which is employed for hardening the fire-proofing material. Its durability is supposed to be due largely to the presence of fire-clay material in the brick. The process of burning in these kilns is such that a quantity of the material is constantly being perfected and removed, its place being taken by the unfinished product. The company keep constantly on hand a considerable quantity of material, so as to be in a position to fill orders promptly.

In another part of the building the visitors were shown the dry pressed brick in process of manufacture. The clay beds from which the brick is manufactured are located at Napanee. The clay, after being dried out and then ground to dust, so fine as to be capable of passing through the finest seive, is conducted to the press, where it is subjected to a pressure of 100 tons. The capacity of this department is 11,000 bricks per day. This department of the business, which was established only a year ago, is meeting with encouraging success.

The tests of the porous terra-cotta fire-proofing for which the visitors had been invited, took place in the open yard of the works. A number of terra-cotta arches of various spans had been loaded with pressed brick for the occasion. It was the intention to add to these loads until the breaking strain should be reached, but it was found that time would not permit, and therefore the additional loading was confined to one arch of six inch end construction, having a span of five feet, and a distributed load to begin with of 630 pounds to the square foot. About an hour was occupied in loading up this arch, the visitors watching the proceeding with much interest, expecting as each additional layer of brick was placed on the arch that a deflection would be noticeable. Examinations were made at repeated intervals, but no deflection took place. After the load had reached 1,000 pounds to the square foot, with no more sign of breaking than at the commencement, the test was considered sufficient, and was not carried further. Details of the tests are as follows:

10 inch Voussoir, 6 ft. span, distributed load, per sq. foot, 968 pounds.

9 inch End Construction, 6 ft. 6 in. span, distributed load, per sq. foot, 633 pounds.

8 inch Voussoir, 5 ft. 6 in. span, distributed load, per sq. foot, 666 pounds.

8 inch End Construction, 5 ft. 6 in. span, distributed load, per sq. foot, 799 pounds.

6 inch Voussoir, 5 ft. span, distributed load, per sq. foot, 612 pounds.

6 inch End Construction, 5 ft. span, distributed load, 612 pounds per sq. foot, 1000 pounds final load.

Since the date of the tests, the loads on the arches have been increased from 500 to 600 pounds to the foot, and are still standing under that strain.

While this test was going on, another of a different character was being carried out a few yards distant. A building, 6 feet 9 inches by 4 feet two inches, by 4 feet 7 inches high, constructed of one-inch boards and lined with one and a half inch porous terra cotta, had been filled with combustible material, saturated with coal oil, and set on fire. The fire burned furiously for fifty minutes without injuring in any way the covering of the building. At the end of that time the fire was extinguished, and some pieces of the porous terra cotta were taken out and immersed in cold water. To the surprise of those who witnessed the test, these pieces of material did not show the slightest crack as the result of contact with the cold water, and nails were driven into them with the same result. It is estimated that a

building lined with this material would prevent fire from spreading for at least twenty minutes, and usually this time would be sufficient to enable the firemen to obtain control.

Several of the architects who witnessed these tests and who had an opportunity of seeing the process of manufacture, expressed their regret that they had not known earlier the character of this material, as they had been importing more expensive and less efficient material for some of their buildings during the past two years.

After having partaken of luncheon, the company entered a special car on the line of railway owned and operated by the Company, and were conveyed to Napanee Mills, where the cement works are situated. These works occupy two large stone buildings about 600 feet apart. They are operated by a 250 h. p. Wheelock engine. By means of a rope transmission device installed by the Dodge Pulley Co. of Toronto, 150 h. p. from this engine is transmitted to the other building, a distance, as already stated, of 600 feet. By means of this device a great saving in power is accomplished. Near these works are located the deposits of clay and marl from which the Portland

cement is manufactured. The clay is peculiarly adapted for the purpose, being free from sand, while the only foreign ingredient in the marl consists of organic matter. The two materials are mixed in the proportion of one of clay to three of marl. They are thoroughly ground together into a homogeneous mass by means of a wet pan mixer. A sample of each lot of material is analyzed before leaving the mixer, to see that the proper proportions of materials are being maintained. Thus every ten barrels manufactured is checked, so that there is little opportunity for variation in quality of the manufactured product. From the mixer the material is carried up by a belt into the pug machine and from thence is loaded on cars and passes into the drying room, where it remains for twenty-four hours. From the drying room it goes to the kiln, and is subjected to a gradually increasing heat, culminating in a temperature of 300 degrees Fahr. The resulting clinker has a specific gravity of 3.13. The material next passes through grinders and three or four pairs of rolls, and is finished on French buhr millstones, which give it a granular finish. The finished material leaves only one to two per cent. residue on a 10,000 mesh sieve. The material thus finished is put into barrels, being weighed separately from the barrel. 350 pounds of material is put in each barrel, so that a uniform quantity of cement is contained in each barrel irrespective of the weight of the barrel.

In connection with the works there is a testing laboratory. The cement is tested by being made into pats on glass, then put in damp air for three hours, then immersed in water for twenty-four hours at a temperature of 130 degrees Fahr. If no signs of blowing are apparent as the result of this test, the material is considered to be of satisfactory quality. Should defects show themselves, it is put back into the bin and allowed to slake off free lime. A briquette made two months previously was broken on the testing machine in the presence of the visitors at 620 pounds, and another, one month old, broke at 450 pounds to the square inch.

The company experienced a great deal of difficulty in the early stages of this enterprise, but have succeeded in so mastering the process of manufacture as to insure a uniformly satisfactory product. The superintendent of the works is Mr. F. G. B. Allan. The works have a capacity of 150 barrels per day.

STUDENTS' DEPARTMENT.

USEFUL HINTS.

In some experiments conducted by the German government on steel and iron girders, the soft steel girder proved twenty-two per cent stronger than the iron girder. The strength of steel girders appeared to be about the same for the two flanges, if made alike in sections.

For filling up the pores of the wood before commencing to polish. For white wood, equal portions of whiting and plaster of Paris, thinned to a paste with turpentine and well into the grain of the wood If for mahogany, add rose pink, or whatever the color of the wood is, and dry color to match up to same.

The following is recipe for paint for ships' bottoms: 8 lbs. of resin, 1½lb. of "Cologne brown dry color," 15 oz. of shellac, 25 gills of spirits of wine, 6 gills of benzine, ¼ gill of toluence, and 10 drops of pyridine. As a finishing coat, a mixture of paraffin wax and white lead "boiled together" is applied hot.

To make plaster medallions look like marble, take pure sweet milk, boil it, and skim it two or three times; put it on the face of the cast, and blow it evenly on all parts, taking care that it does not get on the edge or back; put it aside for two or three days, then put it in a shallow dish face up, and pour in oil of sweet almonds until it comes up to half or two-thirds of the edge of the cast. Be careful that none gets on the face. As the cast absorbs the oil, put in more, until it is saturated. This makes the plaster perfectly transparent and of a beautiful colour. The milk forms a coat on the surface, which will bear washing.

The utilising of waste materials in buildings is not always safe. According to the report of the Chief Inspector on Alkali Works in Scotland, one fatal accident has occurred at an akali work at Irvine, owing to the use of tank-waste as a foundation or flooring, over which had been erected tanks for the condensation and storage of muriatic acid. This material consolidates into a hard mass, and is not unfrequently used in alkali works for filling up hollow places and making good the ground level. It is hoped that the use of this material will be avoided in future in places where it is possible that acid liquors may come in contact with it. In the Irvine case a bricklayer, having to effect some repairs to pipes connected with the acid tanks, was overcome by a rush of sulphuretted hydrogen gas caused by an overflow of the muriatic acid on the bed of tank waste below. The bricklayer fell to the ground insensible and could not be restored.

Yellow pine can be stained to resemble oak in color by very simple means, but if it is intended that the figure should also be imitated, this will be found a more difficult task. A rich dark color can be gained by dissolving 2 lb. of patent size in one pint of water, add some brown umber to give a brown shade, apply while still hot with a brush, and wipe all surplus with a piece of rag. When dry smooth down with a piece of canvas or coarse rag, and fill up all nail holes, &c., with putty colored to match, then wipe over asphaltum dissolved in turps to gain the rich brown (¼ lb. of asphaltum to 1 pint of turps). Allow this to stand till the next day to harden, then varnish with a good quality church varnish. Should it be desired to imitate the figure or grain as well as the color, satisfactory results may be attained by using sizes and ochre instead of umber, and when applying the asphaltum passing a steel graining comb when nearly set and picking out a few light places with a piece of rag slightly wet with turps and held in position over the thumb of the right hand.

It would appear that the external surface of concrete walls will be affected by the character of the timber employed for the temporary framing. In some military works by the United States engineers the plan originally followed was to build all the concrete work with frames of undressed spruce lumber, and then, on removal of the frames, to plaster the exposed surface with cement. This coat of plaster could not be made to adhere to the older work, which rapidly absorbed its moisture, weakening the bond between the two, which was destroyed by the first cold weather, when the coating cracked and dropped off, much to the detriment of the appearance of the work. There was, besides, no economy in the use of spruce lumber, which warped out of shape when subjected to the moisture of the concrete, and could seldom be used more than once, and the plastering was very expensive. It was, therefore, decided to substitute framing made of first quality dressed white pine, grooved on both edges, and united by loose tongues of yellow pine, and to construct the masonary differently. That portion of the concrete next to the frame, 4 inches thick, was laid, and on the frames being removed, a rubbing with a float was sufficient to give a smooth surface to the face. The work was found to resist changes of tem perature without scaling or cracking.

The new Wesley College building in Winnipeg is approaching completion, the exterior work being sufficiently advanced to give some idea of its architectural beauty.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE last of the monthly dinners for the season of 1894-5 of the Province of Quebec Association of Architects was held in the Queen's Hotel on the 4th inst. This dinner was made on the occasion of welcoming back to the city Mr. A. C. Hutchison, 1st Vice-President, after a four months tour in Europe. There was present Mr. F. X. Berlinquet, ex-President from Quebec, and a number of the members. After the dinner Mr. Hutchison gave a brief outline of his trip, dwelling more particularly upon his impressions of the Ancient Greek, Byzantine and Mediaeval styles, as illustrated by buildings in Sicily. He also gave an account of revelations made by late excavations in the arena of the Colloiseum and on the Palatine Hill in Rome.

At the last meeting of the Council, held on the 11th instant, it was decided to hold the semi-annual examinations in Montreal on the 25th, 26th and 27th of July. Thirty days' notice will be required to be given the Secretary by intending candidates.

The following petition has been sent by the Council of the Association to the City Council:

"We, the Council and Members of the Province of Quebec Association of Architects, residents of this city, humbly beg to memorialize the Mayor and City Council, to appoint an Art Standing Committee, to whom all matters relating to the beautifying and embellishment of our city would be referred for their consideration and opinion.

"At present, we believe, there is no special committee delegated to look after this particular object, and accordingly, monuments, statues and other erections are and have been permitted to be put up in our public squares, streets and gardens, that are neither beautiful or a credit to the city.

"Other cities have taken such a step, notably New York and Boston, and have appointed Art Standing Committees of men of acknowledged artistic experience to advise them in such matters.

"Recognizing that taste and a wise knowledge of art requires a special and long training, which it is not in the power of everyone to command, we feel that such an advisory committee would be of great assistance, not only to the city and citizens, but also to the Council as a body.

"If this meets with approval, we would take the liberty of suggesting for your consideration, that this committee should consist of six members, all residents in the city of Montreal, and should include the Mayor and the City Surveyor or Engineer, and a representative from the following Associations:—The Royal Canadian Academy; the Art Association of Montreal; the Association of Architects of the Province of Quebec and the Council of Arts and Manufactures, or such other recognized artistic body as may be selected.

"It is intended that these appointments be purely honorary and with no emoluments attached."

A new granite firm recently formed in St. George, N. B, is composed of Stephen Conley, Owen F. Bogue, James H. Frawley, Caleb Hennessey, James R. O'Brien, Henry F. McDougall and Charles H. Lynott.

The Winnipeg Public School Board propose introducing the best known system of heating and ventilation In several new schools to be erected, and with that object in view invite correspondence from parties dealing in same.

Messrs. Kelley and McCutcheon, two local contractors, have submitted a proposition to the Winnipeg City Council to put in a plant for the manufacture of vitrified brick for paving purposes. A clay suitable for making bricks has been discovered within 150 miles of the city.

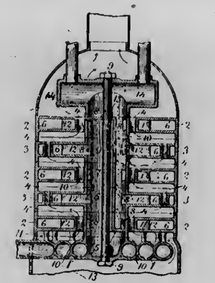
PLAN OF SECOND FLOOR OF HOTEL MAJESTIC, NEW YORK.

FORESTERS' TEMPLE, CORNER BAY AND RICHMOND STREETS. —GEO. W. GOUINLOCK, ARCHITECT.

THE above building, the corner stone of which was laid on the 31st of May, by His Excellency the Earl of Aberdeen, is to be known as the Foresters' Temple, and will be one of the finest headquarters of any fraternal society in the world. The building will be L shaped, with a frontage of 40 ft. on Bay street and 132 ft. on Richmond st., and with a depth north of 108 ft. It will be nine storeys in height, exclusive of a sub-basement, and will cost $300,000.00. The fifth and sixth flats will be occupied throughout by the staff of the I.O.F. The seventh and eighth flats will be fitted up as Assembly Rooms, etc., and a suite of rooms for commercial purposes. The building will be of Credit Valley brown stone and brick and stone facings, and will be absolutely fire-proof; the interior being constructed of steel girders and columns, protected by terra-cotta fire-proofing.

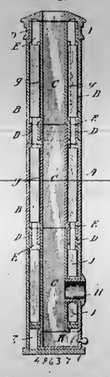
RECENT CANADIAN PATENTS.

No. 48593, for a hot water heater, to Thomas Stubbs Bayles, Toronto, Ont. The accompanying illustration and statement of claim explain the invention:



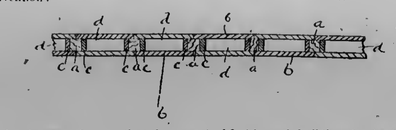
In a water heater, the combination of a spiral hollow section having a well at its centre, a flanged hollow section adapted to fit in close contact with said spiral section and having a well at centre and having a cross wall therein and flues, ports and walls as specified, and a distributing section as specified, adapted to receive a number of pipes therein.

No. 48,637, for a sectional chimney, to William Rollin Wilson and Merton James Bell, assignees of William James Culnan, all of Brule, Wisconsin. The accompanying illustration and statement of claim will explain the invention:



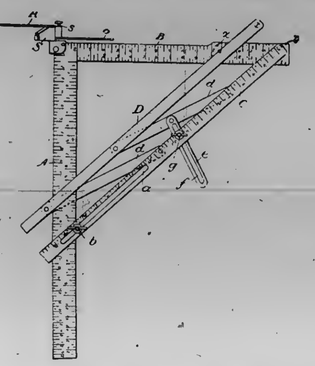
In a sectional chimney, the combination of two or more jointed sections, each section comprising an outer casing and concentrically arranged inner flue, vertical guiding holding beads and removable spacing and holding ribs inserted in the air-space between the inner and outer casing, one end of the outer casing being provided with a joint shoulder and reduced to enter the air-space formed between the inner flue, and the outer casing of an adjoining section and the outer casing provided on its inner surface near its reduced end, with a shoulder which prevents the inner casing from being pushed in too far, and one end of the inner flue being formed with a joint shoulder and enlarged to receive the smaller end of the inner flue, whereby, when one or more sections of the chimney are united, continuous gas tight joints are formed between the adjoining ends of the sections of the inner flue and the connecting ends of the sections of the outer casing.

No. 48,655, for a fire resisting material, to James Day Baker, Montreal, Que. The accompanying illustration and statement of claim explain the invention:



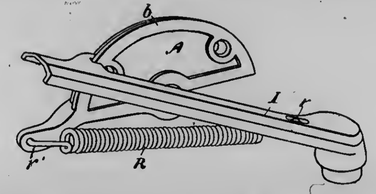
As a means of preventing the spread of fire through buildings having hollow walls, the combination with the combustible vertical studding thereof, of the vertical lengths, e, and the transverse lengths, d, of fire-resisting material with their meeting edges formed to interlock, for the purpose set forth.

No. 48,706, for a roof-framing tool, to John Parkhill, Rochester, Minn. The accompanying illustration and statement of claim explain the invention:



A device for indicating the side cut of rafters comprising a rule or bar adapted to have its edge placed on the plumb cut of the rafter, as indicator plate pivoted to the said bar, to swing at right angles to its length, the said plate having indicating lines marked from a common centre thereof, and fingers pivotally connected with the said plate at opposite sides of the pivotal point and adapted to swing in a plane at right angles to the said plate.

No. 48,743, for a door check, to Henry T. LePage, Toronto, Ont. The accompanying illustration and statement of claim explain the invention:



A door-check consisting of a pivotal plate, the upper edge of which is arc-shaped, a bearing formed in the pivotal plate, a lever; a pivotal pin for the lever working in the said bearing, a pocket in one end of the said lever, a bar connected to the under side of the said lever at or near the said pocket, a guide coonected to the said lever at or near the said pocket, a guide connected to the said lever at or near the said pocket, a guide coonected to the said lever at or near its opposite end working on the upper end of the said plate, a spring having a hook-shaped end encircling the said bar, the opposite end of the spring hook-shaped, and held by the said pivotal plate as specified.

PERSONAL.

Mr. Jos. Lamarche, President of the Montreal Master Plumbers' Association, had the misfortune to break his leg while stepping out of his buggy a few weeks ago.

Messrs. R. W. Thomson, B. A., Sc., and Edgar J. Laschinger, B. A., Sc., graduates of the School of Practical Science, Toronto, have gone to South Africa, where they expect to find promising openings for their energies and abilities.

We observe that Mr. Chas. Baillairge, the talented City Engineer of Quebec, and President of the Province of Quebec Association of Architects, has made request for an increase of salary. It is to be hoped the Council will recognize Mr. Baillairge's able and faithful services to the city during the 29 years he has occupied his present position, by acceding to his request. Such versatility of talents as he possesses are rarely combined in one individual, and at one time or another the City of Quebec has received the benefit of them all.

The death is reported in New York City, on May 16th, of Mr. A. M. Wellington, one of the editors of the Engineering News, and a consulting engineer of great ability and wide reputation. It will be remembered that Mr. Wellington was employed as consulting engineer in connection with the project to elevate the railroad tracks on the Esplanade in the city of Toronto, when the Esplanade improvement scheme was before the Council a few years ago. Mr. Wellington was the author of a number of valuable books on engineering.

BRICKS AND BRICKWORK.*

THE characteristics of a good brick are: 1. Regularity of shape, so that when built into a wall the pressure is equal over its surface. 2. Toughness as opposed to brittleness, *i. e.*, it ought not to snap when broken, but should require two or three hard blows. 3. Clearness of ring when gently knocked against another brick, and not a dull, heavy thud. 4. Homogeneity of surface and texture in the interior, and, above all, absence of small stones or pebbles or lumps of chalk; and 5. Nonporosity, *i. e.*, slowness in absorbing water. I am very much disposed to think the latter quality the most important, and one that is perhaps the least attended to. I mean, of course, with facing bricks. The rate at which a brick—or, for that matter, stone either—absorbs water is a more important element in its goodness than its total absorptive power, because when built in a wall the bricks are exposed only to intermittent wettings, and if in testing two samples of brick I were to find that one absorbed 15 per cent. of its volume of water in the course of an hour, while another absorbed 20 per cent., but took four hours to do it, I should prefer the latter. The crushing strength of a brick is an interesting subject of inquiry, but practically you will find it very rare indeed for bricks to be exposed in walls to anything approaching this crushing strain. Professor Unwin, at the Central Institution, Kensington, kindly tested some bricks for me a few months ago, and it was found that a Leicester brick was crushed with a load of 245 tons per square foot, a Coventry brick at 217 tons, and a London stock at 125 tons, while a blue Staffordshire brick only crushed under a load of 385 tons per square foot, and could not be broken by the machine. A two-brick wall carried up 102 feet high, which is, of course, much higher than would ever be done in practice, would exercise a pressure of five tons per square foot on the lowest course, and this will show you how small is the chance of a brick itself being crushed; but a brick and brickwork are two very different things, the intervention of the mortar joints introducing an entirely new element. Brick piers are very awkward things to experiment upon, and require very special machinery; but some practical experiments upon them have been made in the United States, and you may take it that three tons per square foot in mortar, and five tons in cement, are about the safe loads that should be placed on brickwork.

The reason why some bricks in a clamp or kiln are good and others bad—irrespective of their position—is very difficult to understand even by practical brickmakers, but the most eminent firms are quite willing to admit that they do get a number of bad bricks, and one gentleman told me that out of a very large number of burnings his experience would lead him to the conclusion that 30 per cent. on an average were of an inferior quality. One practical point is never to be guided in choice of a brick by color alone, as it may frequently happen that what looks like an excellent brick may really be as bad as they make them. Knock them together and see how they ring; a bad brick will never ring well, and then break the brick and see its interior. If you see pebbles, or find the interior soft and not of close texture, you may safely condemn the bricks.

Underburning is, I believe, a fruitful cause of inferiority in bricks, as they are then soft and friable; and from my own observation I should say that, if you notice a load of bricks coming on to a job, with a large number of broken ones among them, the chances are that the bulk of the bricks are bad ones, and they should be rejected. This is altogether apart from the risk to the work owing to the temptation to the men to use snap heaters. To revert for a moment to the question of porosity. I believe if in an ordinary wall you were to pour water on the face at a level of about 6 ft. from the ground, none of it would run down as far as the ground; the water would get absorbed before it reached so far; and this with very fair bricks. It may be of interest to you to know of an easy method of rendering a brick wall almost, if not quite, impervious to water. Wash the surface over with a solution of soft soap and water, about half a pound to a gallon, laid on with a soft brush; and, when that has dried in, apply a solution of alum and water, mixed in the same proportions, and the result will be that you have waterproofed the wall. I am indebted to Mr. Rowland Plumb for this recipe.

It goes without saying that however good your bricks may be, you will never get good brickwork unless good mortar is used, and anyone who is in the habit of inspecting old houses will have noticed that in nineteen cases out of twenty it is the mortar which has perished, and not the bricks. In fact, I believe a good brick is just as good after one hundred years' use as when it was new. I am sure the difficulty which public officers have with the speculating builder lies more frequently with the composition of this than with the bricks. The stuff which the 'highly respectable building-man' will try to pass off as sand is of a fearful and wonderful nature. Sometimes he will use sand, but of such a soft, sugary texture, with no sharpness about it, that it is impossible for it to make good mortar. This you can test for yourselves by trying it between your fingers. But I should strongly advise you to look with the greatest suspicion on a heap of brownish grey stuff, which the builder will tell you is road sweepings. I am not saying that in country districts where the roads are mended with granite, if the road-siftings lie in heaps for some months and are carefully washed, you may not obtain a very good building material, but as a rule there is much organic matter in road sweepings, and it is very easy to mix garden loam with it, which is, of course, utterly unsuitable for mortar. Another thing that men will often try to use for mortar, especially in a building which is to take the place of one recently pulled down, is the siftings of the old lime mortar and plaster which has come from the debris of the old houses. Sometimes you may spot this unmistakably by the smell, as I myself once did, a heap smelling very strongly of stale smoke from chimneys. As to lime, it is utterly impossible to discuss this question at the fag-end of what I fear has been a terribly long infliction on you—it would take an evening to itself. I can only say I much wish it were more frequently the practice to build with cement-mortar. I am sure that cement and good sand mixed with 5 and 1 would make better work than ordinary lime and sand mixed 3 and 1, and the latter cost would not be very great. There is one thing that you should be on your guard against in country districts—never allow any brickwork to be built in chalk-lime mortar. It never sets in the interior of the joints. As to the joints, except in winter, I should always prefer to have the joints struck as the work goes up, rather than raking them out and pointing afterwards. There is always the risk of not raking the joints out far enough, and the chances are that the pointing will not adhere to the mortar in which the bricks are laid. Whether you have a struck joint or a pointed one, insist upon having it cut in at the top of the joint, and not at the bottom. The men will always do this if they are explicitly told to, but if not they will always cut it in at the bottom—why, I have never been able to understand—giving a lip on which the water collects. In hot weather you must be careful to dip the bricks in water before laying them, or they will absorb the water far too quickly, and prevent it setting properly.

In this country it can very rarely fall to our lot to be allowed to carry out a commission on those ideal conditions which Mr. Brydon so humorously alluded to in this room, when criticizing the students' work at the Institute, viz., where cost is no object. Economy and utilitarianism are the conditions under which much of our work has to be carried out. We must often, therefore, be compelled to give up the use of stone and fall back on brick. But do not let us on that account despise our material. It is a good honest material, which lends itself to an inexpensive decorative treatment of a perfectly legitimate kind, and I can only hope that in this short paper—the deficiencies of which I am fully conscious of—I may have given you some reasons for not neglecting the study of the history of brick in the past, and I am confident that such a study will be productive of nothing but good in its results on the brick architecture which you will have to construct in the future.

* Abstract of paper read by Mr. John Slater before the Architectural Association, London, England.

THE Port Credit Pressed Brick and Terra Cotta Co. have removed their Toronto office from 52 Colborne street to No. 28 Victoria street.

The Ryan estate, Coldwater, Ont., is constructing a new residence. Mr. Croker, of Orillia, is the architect, and the work is being done by Mr. Eaton, of Orillia.

In the town of Barrie, Ont., W. A. Boys, Dr. Richardson and Geo. Overs are each erecting new residences. Their respective cost will be $3,500, $2,500 and $1,500.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 7. JULY, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods,
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

AT the convention of the National Association of Master Plumbers of the United States, held last month at Philadelphia, Mr. John Date, of Montreal, was introduced as the representative of the Montreal Master Plumbers' Association, and a communication from the Montreal Association was read expressing a desire for affiliation with the American organization. Mr. Date was cordially received, and there is no doubt but that his presence at the convention will tend to promote good feeling between the master plumbers of the United States and of this country. Mr. Date will also no doubt have gathered some information which can be used to advantage in the work of the Canadian organization. At the convention referred to, a resolution was passed requesting manufacturers to discontinue the practice of selling goods to persons who are not legitimately in the business. The definition of a "Master Plumber" agreed to by the Association was: "An individual who represents the industry of plumbing in its most complete state, that is to say, that he must be the proprietor of a plumbing establishment who deals in the merchandise used in the various branches of the business; who engages in trade with the public generally; who hires a requisite number of men, for the purpose of practically constructing plumbing systems in buildings everywhere, and is himself responsible for the work accomplished."

DOUBTS of a serious nature are obtruding themselves into some minds concerning the value of asphalt as a material for permanent street pavements. The city of Toronto has spent upwards of a million dollars on asphalt pavements within the last five years. Some of the pavements thus recently constructed are already full of cracks and holes. This is especially true of those on streets traversed by the street railway. The constantly recurring vibration from the passing cars appears to result in disintegrating the asphalt covering, patches of which become separated from the concrete foundation, leaving here and there ugly appearing and dangerous ruts. Even on streets where there are no street car tracks the pavements show numerous cracks and depressions. It is noticeable that in the first pavements of this character laid in Toronto eight or ten years ago, these defects are not to be seen, which is regarded as evidence that either greater skill or care was exercised in their construction. The statement has recently been made that the frequent sprinkling of the pavement in summer causes it to become rotten and greatly tends to shorten its life. As to the correctness of this statement we do not presume to speak. If it is well founded, then in deciding upon the extensive use of this pavement one of the most important requirements was overlooked. While in appearance and in several other particulars asphalt is the ideal of what a pavement should be, unless it can be made more durable than it gives evidence of being on some of the streets in Toronto, it will not repay its cost. At London, Ont., where a considerable amount of paving is to be done, this question appears to be receiving the careful attention which its importance demands. It is by no means certain that a well constructed macadam roadway will not eventually supersede some of the pavements which have recently come into favor.

THE difference between the estimates for the year of the appropriation required by the Boston Public Library and the amount voted for this institution by the City Council, is such that after expenses and salaries are paid nothing will be left for the purchase of books. This suggests the question as to how much in our public libraries is spent for the mere amusement of the public in the purchase of novels. We think that in the interest of the city, for the education of its inhabitants, for the study of those who earn their living within the city, a very small proportion of the sums expended on books should go to the purchase of "light literature." Professional associations often have their own libraries, but not always, and it is very seldom that the mechanic is able to obtain at his own cost the books he requires for the necessary theoretical knowledge. Such people's needs ought to be the first consideration, and the purchase of novels a very secondary one.

THE rights of "adjoining owners" to support from abutting buildings or even from the soil of the adjoining vacant lot is a matter of more or less consequence to everyone connected with building. It is most important for the owner of the buildings to be torn down, or of the vacant lot in which it is intended to excavate for foundations, to ascertain for his own satisfaction what rights, if any, the adjoining owner possesses, and in all cases where such rights exist he must give ample notice to his neighbor so as to allow of his shoring up his premises if necessary, but it devolves upon the adjoining owner to prove his claim to support. In the absence of any right of support, if on receiving notice he fails to protect his own building from injury, and reasonable time is afforded him for doing so, he cannot claim damages for injury if they occur. In the same way, should the owner of the vacant lot desire to excavate below the foundation of his neighbor's wall, the neighbor must see to his own protection. If the wall is a party wall, the adjoining owner undoubtedly possesses right to support as far as the half wall and the soil supporting it is concerned. The position of the architect or the builder depends very much upon the nature of their employment; to be free from consequences it is often less costly to them to give the notices themselves, or to have an understanding with their employer that he takes all responsibility himself, and that they are acting only and entirely on his instructions. Where they are acting as agents of the employer, the employer is of course responsible for their failure to notify the adjoining owner, but it might be very difficult for them to free themselves if he took action against them to recover the damages paid by him.

THE case of the Dominion Government against Mr. St. Louis, the contractor for the labor supplied in connection with the building of the Lachine bridges, has dragged on its course through different trials in such a way as to mystify the ordinary observer. The case will form a precedent and carries many lessons with it. But the principal point is the further evidence adduced in reference to day labor as opposed to contracts, and it will now undoubtedly be generally admitted that the system of day labor leaves so much latitude for fraudulent transactions that it is hardly wise to resort to it, when it is at all possible to have the work done under contract. The Government was not aware of any negligence on the part of the contractors until the works were far advanced, but the moment it felt its ground sure, it took very decided action. The engineers were dismissed; $60,000 claimed by Mr. St. Louis on account of the works was refused; suit was entered for the return of money said to be already overpaid, while Mr. St. Louis himself was prosecuted for false pretences. The Government was successful in withholding the $60,000, but it failed in the criminal prosecution, and the further case for the return of the over-payments came abruptly to an end by the action of the grand jurors in bringing in "no bill." Sufficient evidence was adduced in the criminal trial to show that an enormously unnecessary force of men was employed, that pay was drawn for men who did not work at all, while many other men who were also paid in full were proved to have done very little for their money. A typical case was that of one witness who actually worked 30 hours and was paid $6.00. In the pay lists, however, his name appeared as having done 320 hours' work, but as many carters had more than one rig and the drivers were careless about giving their correct names or numbers, it was very difficult to trace payments, and hence the decision of the Magistrate that all the fault did not lie with Mr. St. Louis.

IT is not uninteresting to note the arrangements made for the safety of the public in the event of fire in the Albert Hall, London—the greatest concert hall in the world—and to compare them with more modern plans. It was stated in a paper on the construction of the Albert Hall, that was read before the Royal Institute of British Architects many years ago, by Major-General Scott, the engineer of the design, that the corridors that surround the hall, with the crush rooms and staircases, together afford sufficient space for all the people which the auditorium and orchestra will contain, to be in movement at once without jostling each other. The central seating capacity of the hall is given at 8,365, which includes the orchestra and the "picture gallery" that runs round the hall over the corridors and at the back of and above the "balcony." The sum of the widths of the external doors for these 8,365 persons is divided between twenty-five entrances, of which one is 16 ft. wide and all the others 4 ft. 6 in., being one foot to every 64 persons. The capacity of the "picture gallery" is put down at 2,000, but on "great nights" there have been as many as 3,000 persons up there, although only two rows of chairs are provided against the balustrade that overlooks the hall—those who cannot obtain a seat promenading, without being able to see down on to the stage. On such occasions there would be from 10,000 to 11,000 present in the hall, and then the calculations for the 8,365 are naturally found insufficient; and although every person could leave the hall and be accommodated in the corridors, the pace at which one went down the stairs was, roughly speaking, about one step in three minutes. Nowadays, doors for exit, even though there are twenty-five, only 4 ft. 6 in. wide, would be deemed a decided error, for in a panic the public usually follow the leaders like sheep, and all would make for one 4 ft. 6 in. doorway. There are sixteen staircases 6 ft. 6 in. wide, and two 4 ft. 6 in. wide, open to the same objections as the narrow doors. The calculation is one staircase for each 200 persons from the boxes and arena, and for the balcony and picture gallery one for each 500. The amphitheatre has one exit for every 250 persons, each 9 ft. wide.

CRUSHED GLASS AS BUILDERS' SAND.

COMMENTING upon the suggestion of a correspondent that crushed glass should answer as a satisfactory substitute for builders' sand, the London Builder says:—"The suggestion is not altogether novel. In the United States refuse from glass works is sometimes used both for mortar and cement, though we believe its employment is being restricted. In Germany and Switzerland various proposals have been put forward from time to time to employ glass refuse for building purposes, but they do not seem to have come to much for reasons that will presently be seen. There can be no question as to ground or crushed glass being suitable for mortar. Judging from the sample sent us, the small fragments are angulate, and from the mechanical point of view, they leave nothing to be desired. From the chemical standpoint also there is practically nothing detrimental in the material, though it cannot be quite as durable as pure quartoze sand. The chemical composition of black bottle glass varies exceedingly within certain limits, but it may generally be regarded as being from 50 to 65 per cent. of silica, 20 to 25 of lime, 6 to 9 of potash or soda, and from 4 to 7 of iron—depending on the manufacturer and the class of bottle. Ordinary bottles would have about 54 per cent. of silica, 20 of lime, etc. In any case large proportions of lime, soda and potash are present, though the bulk of the glass is silica. From the state in which these ingredients exist in the glass, there is very little likelihood of their being able to materially influence the action of the mortar in any way. We cannot see therefore why glass sand should not be employed in the manner suggested; it would be purely a question of cost. The reason it has not been adopted to any extent abroad—and this is a point for our correspondent to note—is because with very little preparation it makes a good brick for use in chemical works, as the material is so little attacked by acids. Bricks thus produced have a specific gravity of only 1.5, and are very strong though somewhat brittle. A glass brick, in the shape of a flask, has been manufactured in Switzerland for some years, and slag bricks are well known."

THE BYSTANDER.

As a back ground to the most esthetic callings is found after all a strong scent of shop. Agassiz, the famous naturalist, once rebuked a friend of material tendencies, who thought he might turn his tastes to better money-making account, by saying that he had no time to make money. Everyone will admire the devotion of this great man to his calling; but, whilst artist and naturalist, or one engaged in any vocation, may have chosen such because of the love of the work, and do their work from day to day because they love it, yet it is true there is danger of the edge being taken off this devotion, if the calling does not also prove a means of providing bread and butter. The artist who finds no market for his work of brush or pencil is apt to lose much of that inspiration and enthusiasm that is one of the first elements of success in art. So, there is nothing remarkable in the statement of the Bystander, that in moving around among those engaged in architectural pursuits he finds them ready to discuss the business side of the situation, equally as much as the esthetic. That they possess a strong business instinct the Bystander has sometimes thought has been a help to their success. In the architect must necessarily be combined the taste of the artist and the skill and shrewdness of the business man. Designs prepared for the finest buildings must go into the hands of contractors and be put into execution, ere the work of the architect is shown to its fullest advantage. And this will not be done properly unless he has that business instinct that enables him to deal in a business way with contractors and others.

× × × ×

Talking the other day with Secretary Phillips, of the Builders' Exchange, Toronto, the Bystander formed the impression that the past month has taken on strength in building directions. Work is getting better forward in many of the large buildings replacing those recently destroyed by fire. Additional to these, Mr. Phillips said, the fact that contracts are now out for the the work sanctioned by the Public School Board, as also for the erection of the new building of the Toronto Lithograph Co. and others that might be named, has given a fresh zest to building operations. Queried as to the discontent in labor circles, he said that there was no change in the situation within the month. Apparently contractors, as work has increased, were able to secure all the labor that was required, and each was going on the basis of making his own arrangements with bricklayers and other workmen. That this open arrangement will in the end operate against the interests of labor seems more than likely. When trade slacks off it seems to the Bystander, workmen will see the mistake made in not coming to a reasonable arrangement with employers, based on the conditions of the business and labor world as it exists today. But the more thoroughly one looks into this question, at least this has been the result of observation and study by the Bystander, the clearer does it become that few classes of the community are more short sighted and constantly stand against their own advancement than the average workman. He has always a grievance, and is constantly in a ferment; at the same time he is seldom in a position to listen to reason and recognize that conditions change from season to season, and year to year, in the labor world as they do in the economy of nature and elsewhere.

× × × ×

Were the erection of tall buildings, or, as they are familiarly known, sky scrapers, as common in Canada as in the country to the south of us, there would be more interest felt in the remarkable advance that has been made this season in the cost of structural steel. "Where other building materials are somewhat depressed," remarked Mr. Edmund Burke to the Bystander, "steel is going up in leaps and bounds." Perhaps the only building of consequence in Toronto, where a large amount of steel will be used, is that of Mr. R. Simpson, Toronto, with less or more used in the Globe building and some others; but contracts for the steel in these cases were fixed before the present large advance took place. The time will come, no doubt, when there will be many more of these steel buildings erected in Canada. Where they have their disadvantages, and some of these have been brought home closely to the people of Toronto, there is also much to be said in their favor. And the close study that is being given to this class of work is an evidence that steel structures will become an institution of all large cities in the near future. The best architects and knowing builders, it is said, now see that every piece of steel is carefully tested and if not up to the standard they are thrown aside. Experts are hired and controlled frequently by the architect at the cost of those who put up the building. So exacting has this work become that two concerns in Pittsburg are making a specialty of furnishing experts to supervise and are doing the principal work of this character in the country. The Builders' Gazette, of Pittsburg, Pa., summarizing some comments on this subject, has this to say: "In steel frame construction the skeleton of the building is generally erected first, before the masonry is started. Under the old method the iron and masonry were used together in the building of each story. Where bolts were used largely in the last mentioned form, the steel sections are riveted almost wholly in the first. A steel thus riveted can be compared to an inverted bridge, for in fact the modern building is built on the bridge plan, and it is riveted in such a manner to make it, to all intents and purposes, one piece of steel from top to bottom. Thus any strain which may be put upon the building will be shared by the structure as a whole and not confined to any one spot, as in the ordinary building." As the Simpson building advances, and the Bystander understands that the erection of the steel pillars and girders will commence at once, no doubt progress will be watched closely by everyone interested in building operations, as features of construction, that will be to some extent new to our people, will be developed.

× × × ×

The Bystander has been pleased to observe, in the interests of the lumber trade of Canada, that the yellow pine of the southern states, which at one time appeared to be securing a good foothold in building operations here is losing in favor. This change has been brought about, in part, by the action of Canadian lumbermen, after the recent big fires in Toronto, when the attention of all concerned, and the insurance companies in particular, was drawn to the fact that because of the resinous nature of this wood, it was more inflammable than Canadian white pine, and was therefore less deirable for building purposes. One result of this enquiry has been that yellow pine does not occupy the same place in the specifications of architects; and in large buildings now being erected in Toronto, Canadian dimension timber will be almost entirely used. An Ottawa dispatch to the Canada Lumberman also carries some information on this point. It is there stated that an Ottawa firm made the experiment of bringing southern pine into that city, but discovered that although they were not at any loss, yet they did not consider that there was anything gained and have decided to stick to home manufacture for the future. Where the products of the forest are one of the richest resources of the country, there ought to be a pride taken in giving Canadian woods a preference in every case, unless there is some remarkably strong reason for an adverse course.

MASONIC TEMPLE.—R. MACKAY FRIPP, F.R.I.B.A., ARCHITECT, VANCOUVER, B. C.

INSANE ASYLUM BUILDINGS, BROCKVILLE, ONT.—KIVAS TULLY, C. E., ARCHITECT.

FOREMAN AND WORKMAN'S HOUSE TO BE ERECTED ON THE COLDSTREAM ESTATE, NEAR VERNON, B. C., FOR HIS EXCELLENCY THE GOVERNOR GENERAL OF CANADA.—R. MACKAY FRIPP, F.R.I.B.A., ARCHITECT, VANCOUVER, B. C.

A judgment has been rendered at Montreal, in the case of Mrs. Thomas vs. the estate of the late Duncan McIntyre, awarding the plaintiff the sum of $1,400. The widow of the late Mr. Thomas, architect, of Montreal, sued to recover some $38,000 for services rendered by her husband to the late Mr. McIntyre. There were six items, one for $60, three for $2,800 each in connection with a proposed house on Peel street, one for plans for stable, and another item for services in connection with a house on Drummond street. The judge fixed the amount at $1,000 for the Peel street house and $400 for the stable, dismissing the other claims.

CHARACTER SKETCH.

E. H. KEATING,

CITY ENGINEER OF TORONTO.

"We put too much faith in systems, and look too little to men."—B. Disraeli.

PERFECT as may be the plans laid and the system under which work is performed, without men of character and determination to carry out the work, failure is very likely to follow. Many an important undertaking has been spoiled because the man in charge has lacked, not so much the knowledge, but the administrative talent enabling him to bring it to a successful issue. And as one views the administration of municipalities and governments, this seems to be a marked weakness.

These were conditions that were widely discussed, when in 1892 the citizens of Toronto found it necessary to appoint a City Engineer in succession to Mr. William Jennings, who had resigned from this position. The experience of the past three years would lead to the conclusion that in fixing a choice on Mr. E. H. Keating, no mistake had been made, and the weaknesses that in some respects had been feared are not likely to develop in this appointment.

Mr. Keating is a Nova Scotian by birth, and some of the circumstances that influenced him to leave Duluth, Minn., and accept the office of City Engineer of Toronto, furnished evidence that he was possessed of a strong Canadian sentiment, and that love of country to no small extent induced him to return again to the country of his birth. Mr. Keating was born in Halifax, N. S., in 1844. He was a school-mate of the late Sir John Thompson at the Common School, and later at the Free Church Academy. He completed his education at Dalhousie College, entering shortly after that into the calling that he had chosen, serving for some time under George Wightman, the government engineer.

E. H. KEATING,
CITY ENGINEER OF TORONTO.

Railroad building in Canada has proven a useful field of education for many of our best civil engineers. Mr. Keating's predecessor, Mr. Wm. Jennings, owed no little of the success he has attained in after life to the opportunities for development in his profession that were offered during his connection with the Canadian Pacific Railway. Mr. Keating took part in the survey of the Pictou Railway in 1867, under that famous engineer, Sandford Fleming. A little later he was appointed assistant engineer of the Intercolonial, then in process of survey. For a short time he was draughtsman on the Windsor and Annapolis, and then he returned to the Intercolonial during the construction period.

In 1870, when the work of surveying was entered into on the highlands between Hudson Bay and Lake Superior, for the Canadian Pacific, he again engaged under Mr. Sandford Fleming, and did good service in this particular work. In the same year the position of City Engineer of Halifax was offered him and accepted. This position he held from 1871 to 1890, having charge of the construction of many important civic works, particularly the water-works and the Halifax graving dock. These years were useful in obtaining a knowledge of civic management that stood him in good stead in positions of a similar kind, though of an enlarged character, that he held in after years. His arrangement with the City of Halifax enabled him to engage in other work aside from the city practice, and evidence of his skill and ability in engineering directions is scattered throughout the province of Nova Scotia.

In 1890 the people of Duluth were in want of a City Engineer, and the position was offered to Mr. Keating entirely without solicitation. He accepted it, remaining there until July, 1892, when he became City Engineer of Toronto. The reluctance with which the citizens of Duluth severed the official connection was a high compliment to his sterling worth and splendid abilities.

Mr. Keating's work in Toronto during these three years is before the people. Some of the most important undertakings entered into by the city have been completed within this period, under Mr. Keating's direction. The changing of the street railway system to electricity and remodelling the water-works department take a first place among these. It has called for vigorous watching to see that the arrangements between the Street Railway Company and the city have been faithfully carried out, but Mr. Keating has been equal to the occasion. The water-works plans have not really reached the ideal that the Engineer has before him. He believes that a tunnel, such as was described with some detail in the ARCHITECT AND BUILDER two months ago, is necessary to the success of the system. The citizens by their votes have declared against this, though there is no reason to suppose from any want of confidence in the Engineer, but rather because of the heavy burden of taxation that is being borne by them at the present time, and, perhaps, not without some misgivings, though they believe the Engineer to be a strong man, that his municipal advisers are not all possessed of the same measure of back-bone.

As the executive head of the most important department of civic management, Mr. Keating has shown himself possessed of that tact and diplomacy necessary to one occupying a place of this kind. He has also proven himself eminently successful in dealing with his subordinates. "The great art of commanding," said Napier, "is to take a fair share of the work," and Mr. Keating's success as a commander is due, no doubt, in a good degree, to the readiness with which he himself takes hold of the work of the office.

Personally the City Engineer is a very agreeable gentleman. Not given to much talking, he is at the same time always approachable and pleasant. With Wellington he can say that his watchword is "Duty," and to the faithful carrying out of this, other matters must be subordinate.

THE ESSENTIALS OF GOOD PORTLAND CEMENT.

At a recent meeting of the Society of Engineers a paper on Portland cement was read by Mr. D. B. Butler. The author stated that the chief chemical components of a good cement ranged as follows:—Silica, from 20 to 28 per cent., average 24 per cent.; oxide of iron and alumina, from 8 to 14 per cent., average 11 per cent.; lime, 58 to 65 per cent., average 61·5 per cent. These ingredients constituted about 96 per cent. of the whole, the remainder being made up of small proportions of magnesia, sulphuric acid, alkalies, &c. With respect to soundness, the usual test is the moulding of a thin pat with a minimum of water. This pat is allowed to harden on a glass slab, which it should do without cracking. This, the author says, is not altogether reliable, as he had known cases where, though the pat remained sound at the end of seven days, it went to pieces later on. He therefore advocated Mr. Faija's test, which consisted essentially of subjecting a freshly-gauged pat to a moist heat of 100 deg. Fahr. until set, and then placing it in warm water at 115 deg. Fahr. for 24 hours. A pat which stood this test without blowing showed a reliable cement. The edge-runner mills, which were now being largely substituted for stones, did not, he considered, give so large a proportion of the impalpable powder, which is the essential part of the cement, so that a cement ground by stones, and leaving a 10 per cent. residue on a 50 by 50 sieve, was equal in cementitious value to one ground in an edge-runner mill, leaving but half as much residue on the same sieve. From a number of experiments Mr. Butler concludes that the time of setting is less the higher the temperature. Some of the samples tried, when mixed at 80 deg. Fahr. set in half the time required at 40 deg. Fahr., and with other specimens the difference was even greater, and the result was of the same character whether the specimens were tested for initial set or for set hard.

The Canadian Granolithic Company, Ottawa, are putting down a granolithic sidewalk on Clarence and Wellington streets, Kingston.

THE AGE OF BRICK.

DURING the early Christian period, and away down through the middle ages, the majority of public and ecclesiastic buildings were mostly constructed of stone, which in the mild climates of Greece and Italy have not wholly disintegrated, particularly when the stone work has been backed up with bricks. Many of the finest structures of early Christian architecture, that were built of stone, have disappeared altogether, while many of those formed of brick and stone together have come down to us almost in their entirety, while not a single one of the great buildings composed of bricks altogether is known to have disappeared.

In fact, the most perfect buildings that have come down to us from the earliest days, are built of bricks, and we have evidence in a thousand and one instances of the superior lasting properties of bricks over all other known building materials. The Pantheon, the building of which dates back more than a century beyond our era, is built of bricks backed up with concrete, and despite the bandit and barbarian, and the tooth of time, it still remains almost entire, as an object lesson in the use of bricks. The great Gothic Church of San Stefano, Venice, though badly designed and worse constructed, shows the bricks of which it is built to be as sound and shapely as when first laid, though held together by a very inferior mortar.

The Triumphal Arch erected at Rimini in honor of Augustus, is partly constructed of bricks, and partly of marble; but while the marble is nearly rotten and dropping to pieces, the despised bricks remain perfect, and hold together the whole structure and its decaying aristocratic veneering.

By far the oldest Pyramid is of brick, the one of Sakkara, said to have been erected more than a thousand years before Jacob wandered into Egypt. It still holds together and gives promise of being a thing of mystery for a few thousands of years more. Indeed, we believe the Pyramid of Sakkara is supposed to be the oldest structure known. The Temple of Thebes, and the great Pyramids of Ghira, are modern by comparison.

For many reasons brick seems to be the best and most natural of building materials. It is easily handled, materials for its manufacture are abundant and readily obtained, no extra skill for the manufacture of the plainer sort is necessary, it can be moulded to any shape, it is better than stone inasmuch as it is a better non-conductor of heat or cold, it is drier, weathers better, will resist the action of frost and fire better, is lighter, and when well made will resist nearly as much strain as our best building stones. It can be carved if necessary, with a definiteness almost equal to most of our stones, and its economy places it within the reach of medium-sized purses.

Recent improvements in the manufacture of pressed bricks give the modern architect and builder a decided advantage over their predecessors in many ways. In olden times the architect was obliged to have all his moulded and ornamental bricks made by inexperienced workmen, under his own supervision. In the construction of a large building of brick, the brick-maker was one of the architect's staff, and made his bricks to the order of his superior. His appliances for making and burning were of the crudest sort, and, as we know from examination of old bricks, they were often badly made and badly burned. To-day the architect may choose his bricks from catalogues, making his own choice of shape, quality and color, and can rely on getting what he orders; and he can order to suit his design, whereas the old builders were obliged in almost every case to make their designs to suit the materials available.

Canada—Ontario at all events—is well equipped so far as modern bricks are concerned, and speaking from a knowledge born of long experience under several flags, the province named produces a brick that has no superior, and few equals on this continent. Specimens of bricks now before me, made on the Don, near Toronto, from Credit Valley, from the yards at Milton and Beamsville, are fully up to all required standards, and while they vary somewhat among themselves, both as to quality and color, any one of them is superior to the bricks of our grandaddies.

That the coming cities and towns of this great Dominion will be made of brick, goes without saying; even the streets hereafter will be of brick, and it is within the range of possibility that some method will ere long be discovered or invented by which strong slabs of brick or terra-cotta will be made that can be serviceable for sidewalks. This is an "age of brick," and the possibilities of the fertile art are beyond the comprehension of ordinary mortals.

One thing before closing. Some steps should be taken by brick-makers to have one uniform size throughout the whole Dominion. I find, in comparing different makes, quite a difference in sizes: in length, width and thickness. One-eighth of an inch difference counts up in a large building, and frequently confuses an estimator, particularly if he figures closely. Again, the bricklayer finds it difficult to work in pressed bricks with common ones, as the latter are nearly always larger than the former. A standard size would be a boon to all builders, and should be of importance enough to warrant legislation, if the brick-makers themselves do not agree upon a uniform size.

F. T. H.

Collingwood, July 3rd, 1895.

THE PROPER SHAPE OF CHIMNEYS AND FLUES.

THIS question has been considered by a man of a wide and successful experience, and answered very positively as follows:

"Having an idea that it was not all uphill work in a chimney, I concluded to investigate the operation of the one in my house, to see if there were any down currents in it, as I heard frequently asserted. I took light tissue paper and made some small light balls of it. I was particular not to crush them tight and make them heavy, and also was careful to keep them round. With these I went to the top, and balls that were dropped into the center of the chimney were invariably blown out. Those dropped into the corners in a majority of cases went to the bottom, where I found them on taking out the pipe to look for them. Those that did not go down, I think, struck some projection, and were thrown into the central up current and were blown out. This settled in my mind that rectangular flues were wrong, and while the area of a round flue of the same diameter might be less, it was equal in air carrying capacity, as it had only one up pressure, with no corners for friction and tendency toward a vacuum. This led me to making the ends of my partition hot-air flues round, and, while they are easier to make and cheaper, they are equally as effective as if they had square corners, satisfying me that all flues should be round."

From another experienced source comes this idea: "I believe that the house with round flues can be heated satisfactorily for the six months necessary with at least a ton of coal less, where the house with square flues would not be as comfortably warmed."

COLORING ARCHITECTURAL TERRA-COTTA.

THERE is no device resorted to by the clay-worker that is alike so inartistic and so ineffectual, says the British Clay-Worker, as attempting to give to architectural terra-cotta blocks a finer color than they naturally possess. The coating of such blocks with pigments or washes, or the staining of their surfaces, is never of a lasting nature; it soon wears off under the combined action of rain, smoke, frost, and other influences of an atmospheric nature.

"Then what are we to do if our clay will not yield a good color?" some may say. Well, the only course open is to determine whether it is admissable to use chemicals in the composition of the blocks, so that increased tone of color shall be due not to a superficial film, but to the mass itself. Obviously, this will be governed entirely by (1) the cost of the chemicals, (2) the facility with which they can be applied; and these conditions, again, will be governed by the price which can be got for the goods.

If the selling price warrants the expenditure of labor and chemicals, by all means color the mass throughout; but if, on the other hand, the extra labor and expense would not be recouped, it is clear that the best course to adopt is to abandon the manufacture of the blocks, for which the particular clay is obviously unsuited, and exploit the clay for other purposes.

Washes and stains, however, are never permanent, and permanence is the first quality that is demanded in architectural facings. If these principles were more often present in the minds of clay-workers, we should not see so many ghastly failures in our streets, failures which only tend to bring our industry into disrepute.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

MONTREAL may be called with some appropriateness, in a few years from now, the City of Monuments, if their number continues to grow out in the same proportion they have been during the last few years.

Two of these monuments having been unveiled recently, the readers of the CANADIAN ARCHITECT AND BUILDER will forgive me if I take advantage of the actuality of the subject to bring the same before their notice.

Amongst the monuments and memorials the Maisonneuve Monument stands foremost and unrivalled by anything yet erected in the city. It is not that it is the tallest or the most costly, as it is not these alone that are capable of producing a work of art, but it is the refinement of the whole, the agreeableness of the outline and the elegance of the details, which are yet very simple.

The statue stands on a pedestal of granite, having a low buttress at each of its four corners, on which are placed groups of figures, representing Closse accompanied by his dog, and Lemoine, two early settlers of the Ville-Marie; Jeanne Mance represented while attending a wounded young Indian, and an Indian of the tribe of the Iroquois, with which Maisonneuve often had trouble. On each of the four sides of the pedestal are bas-reliefs, the one facing Notre Dame Church representing the signature of the act constituting the foundation of Ville Marie, the one facing the Ontario Bank the exploit of Place d'Armes, the one facing the Bank of Montreal the heroic death of Dollard at the Long Sault, and the side facing the New York Life building the celebration of the first religious service on the island.

The cost of the monument has been about $25,000, nearly half of which has been subscribed by the municipal government and the balance by citizens of the city.

The Macdonald Memorial unveiled shortly before the Maisonneuve Monument, might no doubt be comparable, in respect to its sculpture, to the Place d'Armes monument, but from an architectural point of view it utterly fails to provoke that agreeable sensation and satisfaction one feels when passing by the down-town monument.

The aspect of the whole is of a triumphal arch, standing on a high pedestal, with its two side doorways omitted, and as an architect of some note remarked to me a few days ago, crowned by a candlestick holder. The memorial bears no inscriptions of any kind, with the exception of the name of the great statesman honored by its erection.

The roof is crowned by four lions, and over these by allegorical figures representing the seven provinces of the Dominion, holding a shield bearing the coat of arms of each of the Provinces. The total cost of the memorial was about $35,000.

Another of the monuments also recently erected is a granite obelisk, measuring about 35 feet heavenward, on Foundling street, near Place Royale, in commemoration of the founders of Montreal. The obelisk is perfectly plain, with no sculpture or bronze work, with the exception of the plates bearing the inscriptions, one of which reads as follows:

Le XVIII Mai MDCCCXCIII
Ce Monument a ete erige
par
La Societe Historique de Montreal
a la memoire
Des genereux fondateurs de cette ville
et
des premiers colons arrives ici
en
MDCXLII.

The Historical Society of Montreal is an institution deserving encouragement from all citizens and true patriots, for it is a noble task that it is pursuing. Although the field is not vast in a comparatively young country as ours, we should not lose sight of the great good derived from similar institutions in Europe, and especially in France.

Another monument, and the last I have to chronicle here, is Dr. Chenier's Monument, one of the agitators of 1837-38, which is now in course of erection in Viger Gardens. The foundations are now level with the ground, and it is expected to have it completed this summer.

MONTREAL MASTER PLUMBERS' ASSOCIATION.

The regular meeting of the above association was held on the 20th of June, the President, Mr. Lamarche, in the chair. Among those present were: J. W. Hughes, John Date, P. C. Ogilvie, J. A. Sadler, W. A. Stephenson, D. Gordon, H. Patton, Thos. Christie, W. M. Briggs, D. Sexton, J. Marien, J. Creed, John Watson, F. Horton and G. Denham.

The Secretary read a reply from the Toronto and Quebec associations, regretting inability to send delegates to the convention of the National Association of Plumbers of the United States, held in Philadelphia recently, after which Mr. John Date was called upon to give an account of his visit to the convention. He was courteously received by the American brethren, and found their meetings interesting. About 397 delegates were present, as well as a number of visitors. It was moved by Mr. Gordon, seconded by Mr. Sexton, that the thanks of the association be conveyed to Mr. Date for his services, which was carried unanimously.

After considerable discussion among the members, it was resolved to suspend the regular meetings of the association until September, leaving to the Executive Committee all business arising during the interval, but should it be found necessary, a special meeting may be called at any time.

The hope of those engaged in the building trades has been deceived, for although the outlook last spring for this season's work was satisfactory enough, it appears that, notwithstanding the improvement recorded in trade in general, speculators and money investors are more cautious and prudent than previously, and do not wish to launch themselves in any undertaking of importance until the complete revival of business is assured.

The only buildings of any importance being built this year number only two, the Canada Life buildings at the corner of St. Peter and St. James streets, which has now reached its third story, and the Bell Telephone Co.'s building, at the corner of Notre Dame and St. John streets, which has just been commenced.

PERSONAL.

We regret to announce the death, on the 10th inst., of Mr. Warden King, senior member of the firm of Warden King & Son, Montreal, and one of the most prominent business men of that city. He had been in somewhat delicate health for some time past, but serious results were not anticipated until a short time previous to his death. Mr. King was born in Scotland in 1823, being 72 years of age at the time of his death. In 1852 he entered into business with the late Mr. Rogers, as hardware manufacturers and iron founders, the firm being known as Rogers & King. After Mr. Rogers' death, Mr. Jas. C. King became a partner, and under the name of Warden King & Son the business has since been successfully carried on, the Chanteloup estate being recently purchased by them. In religion Mr. King was a Presbyterian, being the oldest elder in Erskine church, and one of the founders of the Y. M. C. A. He was a Conservative, but took no prominent part in politics.

USEFUL HINTS.

White lead and zinc whites are valued according to their whiteness, fineness and opacity or density. Blacks according to their tone, lustre, density and staining capacity.

In the manufacture of cement mortar about eight parts of furnace ashes, slag, or coke, four parts of slaked lime, and one of clay, are taken and mixed dry so as to form a cement, which, on mixing with water, sets in the ordinary way. The proportions of the materials may be varied so as to produce either an aerial or hydraulic cement.

French polish, as used in France, is made as follows:—A solution of gum acacia and the whites of two eggs is made by beating these ingredients in a mortar until they amalgamate; then half-a-pint of raw linseed oil, the same quantity of the best vinegar, eight ounces of methylated spirits of wine, one ounce of hydrochloric acid, and two ounces muriate of antimony are added.

A writer in one of the English architectural papers gives what he terms "a very simple method of rendering a wood factory building of greater resistance to fire." It consists in filling the spaces between the studding with "a grout made of sand, lime and a large proportion of sawdust, mixed with water to flow slowly. It becomes quite hard; is a poor conductor of heat, and will not ignite, though it is charred by exposure to an intense fire. This applies to a building already constructed, where it would be a difficult task to remove the sheating or lath and plaster already on the inside walls. Where the studding is already exposed on the inner side, the space is frequently filled with brick, masonry, or large tiles made for such purposes.

CODE OF PRACTICE FOR SUB-ESTIMATING AND SUB-CONTRACTING.*

THE Master Builders' Association of the City of Boston, recognizing the importance of defining the rights and obligations of Principal and Sub-Contractors for Building Work, in their relations to each other in estimating, contracting for, and carrying on work, hereby approves and adopts the following Code of Practice as a declaration of what it will recognize as honorable methods in the conduct of business.

ARTICLE ONE.—Obligation of Principal Contractor to Sub-Contractor.—A principal contractor is under obligations to treat upon an equal basis all estimates which he "received," prior to putting in his own bid. Estimates must be considered as "received" when they come into a principal contractor's possession, either by his direct solicitation or by being accepted by him. The opening of a bid, knowing it to be such, constitutes receipt of the same.

A principal contractor is under no obligation to use a bid which he has not solicited, accepted, or received, but if he does not wish to use the estimate of a sub-bidder he should decline it, if proffered personally, or should return it unopened if sent to him by mail or otherwise. The retention of a bid should be constructed as a receipt of the same.

All bids should be considered "confidential," and a principal contractor revealing any bid received by him to any person whomsoever, without consent of the sub-bidder, will be liable to complaint and discipline under Article X of the By-laws of this Association.

A principal contractor, when making up his estimate, is not entitle to receive bids from sub-contractors if he is at the same time making himself their competitor by figuring their portion of the contemplated work. It is legitimate for a principal contractor to figure all proportions of work, depending upon no one for what are usually know as sub-estimates, but it is not legitimate for him to receive bids from others for sub-work if he is himself figuring those portions independently.

ARTICLE TWO.—Award of Sub-Contracts.—The principal contractor having been awarded a general contract, should immediately award the sub-contracts to the lowest bidder in each branch.

ARTICLE THREE.—Penalty for Not Awarding Contracts to Lowest Sub-Bidder.—A principal contractor, failing to award a sub-contract to the lowest sub-bidder to whom he is under obligation as previously provided, should be liable to pay damages to the said lowest bidder, in amount not less than ten per cent. of the amount of the estimate.

Payment of such damages will not relieve the principal contractor from liability to discipline under provisions of Article X of the By-laws of this Association.

ARTICLE FOUR.—Contracts with Sub-Contractors.—The principal contractor, immediately after executing a general contract with the owner, should, for his own protection as well as the protection of the sub-bidder, execute some satisfactory form of contract or agreement with each lowest sub-bidder.

ARTICLE FIVE.—Payments to Sub-Contractors.—Unless the contracts made with sub-contractors otherwise provide, payments during the progress of the work should be made by the principal contractor to the sub-contractors upon the same basis of payment, in relation to the amount of work performed, as is prescribed in the contract made by the principal contractor with the owner.

Final payment to a sub-contractor should be considered as due at the expiration of thirty days after the completion of his work and its approval by the architect or owner, unless otherwise provided by the sub-contract or agreement.

ARTICLE SIX.—Submission of Bids by Sub-Contractors.—Sub-contractors in submitting bids to principal contractors should enclose them in the envelopes prepared by this Association and kept on hand for the use of sub-bidders, or should endorse the envelopes in which they are enclosed in such manner that principal contractors may know whom the bids are from, what portion of the work they comprehend, and the particular building they apply to.

Sub-contractors who fail to so enclose and endorse their bids cannot claim protection or redress under the first article of this Code.

ARTICLE SEVEN.—Obligation of Sub-Contractor to Principal Contractor.—Should a sub-contractor refuse to contract at the amount of the estimate he has given to a principal contractor who had used the said estimate in good faith, he then should be liable to the said principal contractor for damages in amount not less than the difference between the amount of the estimate which was submitted by him and the amount at which the principal contractor may be obliged to contract the work.

Payment of such damages will not relieve the sub-contractor from liability to discipline under provisions of Article X of the By-laws of this Association.

ARTICLE EIGHT.—Obligations of Sub-Contractors to Each Other.—Any sub-contractor suspected of unfair treatment of his fellow sub-contractors will be liable to complaint and discipline under Article X of the By-laws of this Association.

ARTICLE NINE.—Trading Sub-Bids.—Trading upon sub-bids will be considered sufficient cause for complaint and discipline as provided by Article X of the By-laws of this Association.

ARTICLE TEN.—Bids to Architects or Owners.—When bids for separate departments of work on a building are solicited by the architect or the owner, they should be submitted with the understanding that they are direct estimates, for which direct contracts are to be made by the owner with the lowest bidder, and no other disposition of such bids should be permitted without consent of the bidder submitting the same.

Sub-bids should be given only to the principal contractors who are estimating the work in question, and should not be left with architects or owners for the inspection and information of principal contractors. Sub-contractors must understand that bids thus left with architects or owners are in great danger of losing their confidential character, and that if they so leave them they cannot claim protection or redress under the first article of this Code.

SUGGESTIONS.—Members of this Association having sub-contracts to let or material to buy should, as far as may be consistent with business principles, deal only with members of the Association, or at all events give their fellow-members an opportunity to compete, and then give them the preference, other things being equal.

All bidders should take cognizance of the danger they may be subject to through the practice, so prevalent in some architects' offices, of making changes in plans or specifications, or in both, during the progress of estimating. Correction of this prenicious practice can only be obtained through refusal by contractors to estimate under such conditions.

[A true copy.]

Attest: WM. H. SAYWARD, Secretary, M. B. A.

* [In adopting the Code the Association acknowledges its obligation to the National Association of Builders for valuable suggestions in relation to this important matter.] Adopted August 2, 1891.

GLASS COLORING IN GERMANY.

THE beautiful coloring of certain varieties of glass, now produced in Germany, and which is said to far excel some of the most noted French specimens, is an art practiced by the glass blower at the furnace, by means of an apparatus consisting of a sheet iron cylinder, twenty inches long and eight inches diameter, standing vertically, and having a similar cylinder riveted across the top. Kuhlow's German Trade Review says that in the lower cylinder is an opening into which an iron ladle can pass, and the horizontal cylinder is provided with doors at either end, the one nearest the operator being so arranged that the blowpipes can be supported, when the door is closed, in a horizontal split running to its middle, the object to be treated being held inside. While the glassblower is reheating his work for the last time in the furnace, an attendant takes the long-handled iron ladle, which has been heated red hot, shakes into it about a spoonful of a specially prepared chemical mixture, and places the bowl of the ladle quickly in the opening provided for it in the vertical cylinder. The mixture immediately gives off vapor, which rises to the horizontal cylinders, where, meanwhile, the blower has placed his work, supported by the blowpipe and heated to an even red, turning it rapidly in the vapor. In a short time the object is covered with a changeable lustre, is removed from the pipe and tempered like other ware in an ordinary oven, then cut, engraved, painted, or gilded as desired.

The corner stone of a new English church has been laid at Fergus, Ont.

THE ABUSE OF CEMENT.*

By D. B. Butler.

The treatment which cement sometimes has to undergo at the hands of inexperienced users, makes it a matter for wonder that failures are not more frequent. One of the most prolific causes of failure is insufficient attention to the setting properties of the cement under treatment. In very hot weather it is no uncommon thing for a cement to have a very quick initial set, and in using such a cement, therefore, in order to obtain its full strength, it must be mixed and in its allotted position within a very few minutes of adding the water. This often entails the mixing of very small quantities at a time, and if due precautions are not taken, a larger quantity is mixed than can be manipulated before setting commences. This generally results in the use of additional water, and the serious detriment, if not total destruction, of the setting properties of the cement. Many cases of failure have occurred in which the cement being a good quality, though somewhat quick setting, point strongly to over-manipulation or "killing."

Another frequent cause of unsatisfactory work is a dirty and unsuitable aggregate. The admixture of a very small proportion of dirt or loam is quite sufficient to materially deteriorate the strength of a concrete, and too much stress cannot be laid upon the necessity for seeing that all aggregates are free from any foreign dirty matter. A case of structural failure came under the notice of the author a short time back, in which the cement used was perfectly good, but the finer portions of the aggregate consisted of very fine sand, so fine that .60 per cent. passed through a sieve having 70 holes per lineal inch, and 80 per cent. through a sieve having 50 holes per lineal inch. The structure of which it formed part had to bear a considerable thrust, and to aggravate matters, instead of this sand being properly mixed, large patches occurred in which there was no cement at all. In addition to this, the sand contained a considerable portion of loam or foreign matter, and it is not to be wondered at that failure resulted.

The neglect of the proper cooling or aeration of a cement is a frequent cause of trouble, and to ensure satisfactory work, proper cooling cannot be too strongly insisted upon. Of course cement may give good results when used hot from the mill, and the author has manufactured cement which has turned out satisfactorily under these conditions, but to use cement in this state is to court failure. It is sometimes specified that the manufacturer shall store the cement in his warehouse at a stated thickness of say 3 ft., for a certain period, and have it turned over three or four times at regular intervals before being supplied for use, but if this had to be done with the entire output of every factory, it would necessitate an enormous increase in warehouse room, to cover the first cost of which would entail a largely increased price to the consumer. It it therefore advisable, where cement is being used in considerable quantities, to construct temporary cooling sheds, with a good, dry, boarded floor, where the cement can be turned out in sacks or barrels and thoroughly aerated before use. It is sometimes contended that the cement, even if shipped hot, cools sufficiently during transit. Although it undoubtedly cools to a certain extent, it is doubtful if, when tightly packed in barrels, or closely stowed in sacks, it cools sufficiently to allow of its being immediately used with safety.

The exposure to extremes of temperature has perhaps more to answer for in the shape of unsatisfactory work than is generally recognized. If exposed to a summer sun immediately after being gauged, naturally a great deal of the necessary moisture is evaporated, leaving the cement without sufficient to complete the crystallization already set up. The result frequently is that the work crumbles, and shows signs of failure. On the other hand, exposure to frost acts on the water, and by expansion destroys the surrounding concrete. The author once had occasion to investigate a case of failure in which frost was the undoubted cause of the mischief, as there was no fault to be found either with the cement, aggregate, or manner of manipulation. The concrete flooring of an outhouse in some new farm buildings was commenced late in December, and left partly completed owing to the Christmas holiday. As frost set in with unusual severity during the interval, the work was not revisited until the return of milder weather, three or four weeks afterwards, when it was found that that portion which was laid immediately before the frost, was utterly destroyed, while the proportion previously laid, which had sufficiently hardened to prevent total destruction, showed signs of flaking on the top where it had been floated or trowelled. In this case the cement had to bear the blame, although the destroyed portions, afterwards relaid with the same materials, gave perfectly satisfactory results. During severe weather, therefore, proper precautions should be taken to protect freshly laid concrete from the effects of frost.

To summarize the preceding remarks, the chief points requiring attention in the use of cement, in order to obtain the best results, are the following :—(1) Sound, well ground cement, of steadily increasing strength. (2) Due attention to the setting properties of the cement. (3) Clean, well-proportioned aggregate. (4) Proper maturing of the cement before use. (5) Protection from extremes of temperature. If these points always received the amount of attention due to their importance, failures in cement work, apart from defective design, would very rarely be heard of.

*From a paper read before the Society of Engineers.

APPROXIMATE ESTIMATES.

We have devoted much space in our columns, says The Building News, to estimating buildings, and to the methods in use for taking out quantities; but for the architect's purposes a more expeditious mode of calculation for obtaining approximate estimates is necessary. The ordinary cubing process is open to some objections. The pricing of the voids or spaces with the solid portions is not altogether satisfactory; indeed, without some attention to the proportion between the two, and the character of the building, it is eminently unscientific. Every architect is aware that the open spaces of rooms very materially affect the estimate. A building like a large hall or a place of worship, inclosing one large room, and a building of the same dimensions divided into small rooms, give very different results, and if cubed at a price that would be fair for the first, would be disproportionately inadequate for the latter. It is true that the practical man may so regulate the price per foot in each case as not to go far wrong; but this knowledge requires a large and varied experience. In buildings like hospitals and barracks the proportion of the voids to the solid structure ought to be ascertained before the ordinary price per foot can be arrived at. The author of a paper on this subject, Mr. S. Alcock, surveyor of the Royal Engineer Civil Service, has written some sensible remarks on the question worthy of attention, his remarks bearing more particularly on barracks. He shows that if the cubical contents of the rooms were deducted from the contents of the whole structure, the remainder would represent the cube contents of the actual building materials in the walls, floors, ceilings, and roofs, and a price per cubic foot on this remainder would be a much closer and more reliable approximation to the cost; but as these several parts vary considerably in price, as, for instance, the walls being less per cube foot than the floors, this plan still leaves much to be desired. He suggests a method that has been used by some, that "a much more reliable approximate estimate of the cost might be made by pricing the enclosures or envelopes to the rooms or apartments at so much per hundred square feet, taking the walls according to their thickness and manner of finishing each face, including all digging, concrete footings, plastering, papering, coloring, lime-whiting, etc., in fact, all work and material expended on the walls; and for the dimensions (1) the length, and (2) the height from the bottom of foundations to the eaves if the wall maintains the same thickness throughout, or to the change in thickness if the thickness is changed, and making no deductions for doors, windows, or other similar openings." The floors are similarly to be taken by the square of 100 ft., including all joists, boarding, bridging, hearths, the upper floors to include lathing and plastering, and the ground floor dwarf walls and any concrete to the ground under the boarded floor. The roof covering should include not only the slate or tile, but leadwork, rafters, boarding, trusses, skylights, etc.

This mode of estimating the constructional envelope, instead of taking solids and voids together, is much more reasonable, as it takes into account the materials and labor in a more precise and definite form. By using a schedule of prices calculated for each of these main superficies—namely, for the walls, the floors, and the roof—we can obtain a very approximate idea of the total cost.

STUDENTS' DEPARTMENT.

STUDENTS' EXAMINATIONS.

Following are the subjects for the students' examinations of the Ontario Association of Architects for 1896:

FIRST INTERMEDIATE EXAMINATION.

Every candidate must, at least one week prior to the date fixed for the examinations, send to the Registrar the following drawings, which must be certified by his principal to be his own work :

Five sheets of drawings, one of each of the Roman orders. One sheet of the mouldings and ornaments of those orders drawn to a larger scale. (Each sheet to be of the size of a half sheet of Whatman's Double Elephant paper, i.e., 20 in. by 26 in.)

The subjects for examination will be :

Elements of Construction.—Text book : Mitchell's Building Construction.

Mathematics.—Euclid : Books I, II and III. Plane Trigonometry : Including the solution of plane triangles. Algebra : Including quadratic equations.

Technical Terms.—A knowledge of the terms neces ary to understand the description of a monumental building and its parts.

History of Architecture.—To the close of the Roman period. Books recommended : Stevenson's House Architecture, Vol. I, as an introduction ; Rosengarten's Architectural Styles ; Fergusson's History of Architecture.

SECOND INTERMEDIATE EXAMINATION.

Every candidate must, at least one week prior to the date fixed for the examination, send to the Registrar the following drawings, which must be certified by his principal to be his own work :

One sheet of Romanesque architecture ; two sheets of Gothic architecture ; one sheet of drawings measured from existing examples ; one sheet of constructional details. (Each sheet to be of the size of a half sheet of Whatman's Double Elephant paper, i.e., 20 in. by 26 in.

The subjects for examination will be :

Statics, Graphical and Analytical.

Strength of Materials.—Text book for both the above heads : Lessons in Applied Mechanics, by Cotterill & Slade ; Part II.

Practical Knowledge of Building Trades.—Masonry (excluding cut stone work), Brickwork and Plaster. Text book : Mitchell's Building Construction ; advanced course.

Structural Iron Work.—The candidate will be required to draw details of the forms of iron construction in use in ordinary practice, viz.: the construction of columns and girders, and the framing of beams and trusses. Text book : Mitchell's Building Construction ; advanced course.

History of Architecture.—From the close of the Roman period to the present time. Text books recommended : Fergusson's History of Architecture ; Rosengarten's Architectural Styles ; Parker's Introduction to Gothic Architecture.

FINAL EXAMINATION.

Every candidate must, at least one week prior to the date fixed for the examination, send to the Registrar a perspective drawing which must be certified to be his own work. Drawings to be on a sheet of paper, 20 in. by 26 in., and not mounted on cardboard.

The subjects for final examinations will be :

History of Architecture.—The candiate will be expected to know the history of the development of Architecture.

Mouldings, Features and Ornaments.—The candidate must be able to draw the characteristic mouldings, features and ornaments of any style.

Design.—As illustrated by drawings for a building of moderate dimensions, from particulars given, with details of construction and ornament.

Nature and Properties of Materials.—Limes, cement, stones, bricks, timber. Text book : South Kensington Notes on Building Construction.

Foundations.—Text book : Foundations, by George T. Powell.

Architectural Jurisprudence.—Text book : The law relating to Civil Engineers, Architects and Contractors, by Macassey & Strachan.

Practical Knowledge of Building Trades.—Sufficient for the purposes of ordinary building. Text book : South Kensington Notes on Building Construction ; Building Superintendence, by T. M. Clark.

Strength of Materials.—Designing structures of an ordinary kind from data, with computation of the strains involved. Text book : South Kensington Notes on Building Construction.

Heating and Ventilation.—Text books : Ventilation and Heating, by John S. Billings ; Steam Heating for Buildings, by Wm. J. Baldwin.

Sanitary Science.—Text books : Gerhard's House Drainage ; Bayles' House Drainage and Water Supply.

Steel and Iron Construction and Protection.—Text book recommended : Skeleton Construction in Buildings, by W. H. Birkmire.

PLASTER CASTS.

Plaster of Paris may be hardened so as to bear a more perfect polish than ordinary stucco-work, and not be very readily scratched. This is effected, says the Builders' Reporter, by the addition of certain saline substances, such as alum, borax, silicate of potash, or soluble glass. If an object in plaster, such as a bust, be soaked for a month in a solution of alum in twelve to thirteen parts of water, and then wiped and allowed to dry fully in the air, it will become so hard that it can no longer be scratched with the nail, and will lose much of the brittleness of ordinary plaster casts. Casts treated in this way become stained, and are always liable to attract moisture from the atmosphere. If baked gypsum be moistened with a solution of alum, or raw powdered gypsum be well mixed up with a similar solution and exposed to a red heat, a mass will be obtained of a dull milk-white, or more usually a slight cream color, which may be readily pulverized, and will set quite as well as ordinary gypsum, especially if a weak solution of alum be employed in making the paste. Casts prepared of the compound thus formed, although taking a longer time to dry, are unusually hard. They may be exposed to the weather for some time and may be washed with a sponge without injury, and even immersed in boiling water without diminishing their hardness. Those prepared by steeping in a solution of alum, on the contrary, will become quite soft ; so much so as to receive the impression of the fingers if soaked for a few hours in cold water. Keen's cement is a plaster prepared in this way. If carbonate of potash or pearl-ash be mixed with the alum, so as to form a basic alum, we have Martin's cement ; and if for the alum we substitute borax, we have Parian cement. Common plaster of Paris casts resemble, in many respects, the dense gypsum from which a good deal of the plaster of commerce is made ; and as this differs from alabaster only in its molecular structure, many persons have imagined that it might be possible to convert plaster into a material resembling that beautiful substance. The nearest approach which has yet been made to the solution of this important problem is Cheverton's invention of the so-called protean stone or plastic ivory. This substance, which is well adapted for carvings in imitation of ivory and the manufacture of various ornaments, is made by exposing the plaster cast or block of the same substance to a temperature varying from 250 deg. to 350 deg. Fahr., during twenty-four hours, by which the whole of the water combined with the sulphate of lime is driven off, and the material reduced to the condition of plaster of Paris. After undergoing this operation it still retains its form, but is exceedingly friable.

The following makes a good gasfitter's cement :—Take 4½ parts by weight of resin, 1 part of beeswax, and 3 parts of Venetian red. Melt the resin and wax together, then stir in the red pigment, and pour the mixture into moulds made of oiled paper or iron.

Brick-dust Mortar.—The use of brick-dust mortar as a substitute for hydraulic cement is now recommended on the best Spanish engineering authority, experiments made with mixtures of brick-dust and quicklime showing that blocks of one half inch in thickness, after immersion in water for four months, bore without crushing, crumbling, or splitting, a pressure of 1,500 lb. per sq. in. The use of brick-dust mixed with lime and sand is said to be generally and successfully practised in the Spanish dominions, and is stated to be in all respects superior to the best cement in the construction of culverts, drains, tanks, or cisterns.

SOME EXPERIMENTS WITH MORTARS.

It is a common belief amongst builders, especially amongst bricklayers and foremen, that it is much more advantageous to mix lime-mortar some days before it is wanted, rather than to mix it immediately before the bricks have to be laid.

To test this popular superstition—if we may be forgiven the expression—says the British Clay-Worker, samples of mortar have recently been taken on successive days from two separate heaps of larger size. Small cubes of bricks were moulded from these samples, and set aside for a definite period of weeks, and then broken, in order to estimate their tensile strength.

The following were the results :—

Simple	Days in heap after mixing.	Days exposed to air as a small brick.	Average breaking stress in lbs. per sq. in.
Mortar No. 1	3	50	34·6
" "	4	49	38·6
" "	6	48	38·1
" "	7	46	39·3
Mortar No. 2	4	48	36·0
" "	5	47	38·0
" "	6	46	41·2
" "	7	45	41·5

The amount of calcium silicate formed was found to be exceedingly small, even after very long intervals of time.

Another notion which is very common amongst those who have to deal with the building of bricks into brickwork is that sugar and blood are very good things to mix with the mortars, especially with hydraulic mortars. Consequently, experiments were undertaken to test these views.

Hydraulic mortar tempered with sugar and water, at the rate of half a pound of sugar to a gallon, was found to be considerably stronger than the same mortar tempered with water alone. This was found to be true only if the mortar were allowed to harden exposed freely to the atmosphere. If the mortar were used for sub-squares brickwork, no advantage was found to follow upon making the extra expenditure and taking the extra trouble with sugar.

The same mortar was also tempered with bullock's blood, diluted with one-third of its volume of water. The mortar was then moulded in a brick mould, and was found to set somewhat more quickly. It also showed a considerable increase in strength, both when exposed to the air as well as when laid under water.

Here are some experimental data :—

	lbs per sq. in.
1. Tempered with water alone	63 00
2. " " sugar solution, and exposed to water during 38 days	62·75
3. " " sugar solution, and exposed to air during 38 days	65·4
4. " " diluted blood, and exposed to water during 37 days	68·3
5. " " diluted blood, and exposed to air during 37 days	69·8

So it seems that there is some truth in these old notions ; and those who hold them will now be able to give scientific reasons for their faith.

HOW TO PREPARE MORTAR.

Mr. Edward Wolff writes on the above subject to Engineering, New York, showing defective methods of mortar making employed by builders, and giving the proper method of slacking lime, preserving it in good condition after slacking, and preparing from it strong, adhesive mortar :—

"The slacking operation should be done in a water-tight box made of boards, and so much water should be mixed in that the contents will never get dry, and a sheet of water will remain on top to prevent access of air. If the box will not hold the entire quantity of lime required, the contents may be emptied into a cavity made in the ground close to the pan, and this process may be repeated. This should be done at least two weeks before sand is added, or before the mortar is prepared for use. Slackened lime prepared and kept as stated has been found free of carbonic acid after many years, air and gas having not been able to find access. Instead of following the procedure in slacking lime recommended above, we see in this country, or at least in the neighborhood of New York, a faulty process adopted, which consists in loosely mixing the sand with the slacking lime immediately after water has been added, and forming a dry heap on the surface of the ground, which is left lying there several weeks to give time for complete slacking before the sand is worked in evenly and the mortar considered ready for use. This heap arrangement is perfectly adapted to circulating air through a material which should be guarded against contact with air. The sun heats the surface of it, makes the air escape after it has given up its share of carbonic acid gas, while at the base of the heap and at the shady side, a fresh supply enters to fill up the vacuum after it has circulated through the heap and has been robbed of its share of carbonic acid gas. That this procedure really happens in such a heap we can easily see when we place a lump of freshly slacked lime in a wineglass, and in another glass place a small quantity of material taken from a heap such as described, and which has been prepared a few days before ; fill both glasses nearly up with water, and add a few drops of muriatic or sulphuric acid to each In the first glass nothing can be observed, while in the second glass we will see in the shape of small bubbles the carbonic acid escape, which has been absorbed by the lime from the atmospheric air circulating in the heap."

THE TROUBLES OF INEXPERIENCED CONTRACTORS.

Here in this northern country, writes Mr. Fred. T. Hodgson, of Collingwood, in the Brickbuilder, the winters are long and severe, and bricklayers and masons have necessarily a long spell of idleness, and of course when spring does set in they are anxious to go to work at the earliest moment possible, and in their anxiety frequently contract for work much below its actual value. A case in point has just come under the writer's notice, one of a great number, and was as follows : A strong company in town desired to erect a large brick building for a sort of annex to their extensive meat-curing factory. Plans and specifications were prepared during the winter, and the contracts were advertised to be let about May 1. Nearly all the legitimate contractors tendered for the work, and a bricklayer who had never had any experience with large contracts tendered also. His figures were so low that the company, who thought the regular contractors wanted to swindle them, gave him the work. Everybody knew, who knew anything about such work, that if the successful tenderer went on with the work it would ruin him. He commenced operations, however, engaged his men, and purchased some of his material, when all at once it dawned upon him that he had taken the work too low. Fortunately the papers had not been completed, and he threw the job up. The company tried to keep him to his bargain, and at last offered him a big sum more if he would go on with the work. He concluded to try it again, did so, this time under the knowledge that he was tied down on paper to complete the work. He discovered the other day that even with the addtional sum allowed him he would lose money, so abandoned the work a second time. The company was obliged to have the work done, so were compelled to fall back on the regular contractors, who now command the situation, and the owners have to pay the piper. The first contractor has now got into trouble that may sweep away a lot of money, and he has missed several smaller jobs that were within his capacity as a contractor.

This is one of many like cases that I have met with in my forty years' experience. Men are too anxious to become contractors, and fail to recognize the fact that special qualities are required in a man to make a successful contracor.

PUBLICATIONS.

The frontispiece of the June Review of Reviews—"Prince Bismarck in His Home"—is a striking representation of the family group at Friedrichsruhe.

"Property" is the title of a new monthly publication, the first number of which has reached us. It is declared to be published in the interests of investors in all lines. The publisher is Mr. H. Bragg, Montreal.

The Laughlin-Hough Drawing Table Co. has recently been formed in Guelph, Ont., with a capital stock of $55,000, to manufacture patent drawing tables and boards for architects. The company have just completed arrangements for manufacturing, and the goods will shortly be placed on the market.

An association has been organized by the master painters and decorators of Montreal, with officers as follows : president, John Murphy ; French vice-president, A. Laurin ; English vice-president, J. B. Owens; treasurer, C. T. Charlebois; English secretary, W. T. Castle ; French secretary, F. E. Meloche.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—No. 8. AUGUST, 1895 PRICE 20 CENTS $2.00 PER YEAR.

THE
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1895.

PRESIDENT	FRANK DARLING, Toronto.
1ST VICE-PRESIDENT	THOS. FULLER, Ottawa.
2ND VICE-PRESIDENT	J. GEMMELL, Toronto.
TREASURER	H. B. GORDON, Toronto.

COUNCIL:

D. B. DICK	Toronto.
W. A. EDWARDS	Hamilton.
F. J. ALEXANDER	Ottawa.
J. M. MOORE	London
W. R. STRICKLAND	Toronto

REGISTRAR AND LIBRARIAN:

W. A. LANGTON	Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1895.

PRESIDENT	CHAS. BAILLAIRGE, Quebec.
1ST VICE-PRESIDENT	A. C. HUTCHISON, Montreal.
2ND VICE-PRESIDENT	A. T. TAYLOR, Montreal.
SECRETARY	J. VENNE, Montreal.
TREASURER	JOSEPH PERRAULT, Montreal.

COUNCIL:

J. Z. RESTHER	Montreal.
J. NELSON	Montreal.
A. RAZA	Montreal.
ROBT. FINDLAY	Montreal.
F. X. BERLINQUET	Quebec.
J. B. BERTRAND	Quebec.

AUDITORS—L. Z. RESTHER, W. MCLEA WALBANK.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

CANADA is the scene of some of the greatest engineering triumphs. It is therefore not surprising to learn that an official of the Russian Railway Department visited Ottawa recently by direction of the Czar, with the object of obtaining information touching the best practice in bridge construction.

THE amendments which were suggested by the Master Plumbers' Association to the Toronto plumbing by-law, cannot be incorporated into the by-law at the present time, owing to a recent decision given by Judge McDougall in the Toronto Courts. This decision is to the effect that the City Council has no authority to regulate the size and weight of pipe which shall be used in the plumbing system of a building. In view of this decision, it is understood to be the intention of the City Council of Toronto to make application to the Ontario Legislature at its next Session for authority which will enable a by-law to be passed to govern the manner in which plumbing shall be done.

WE regret to have to record the death on the last day of July, of Mr. Richard M. Hunt, the distinguished American architect. Mr. Hunt held the foremost place among the architects of the United States, and was the recipient of high honors from foreign societies. His art training was received at the School of Fine Arts in Paris, and for a time he practiced his profession in that city. He afterward returned to America and opened offices in New York city. In New York, Boston and Newport are to be seen many examples of his skill. He was the designer of the Administration Building at the World's Fair. He more than once occupied the position of President of the American Institute of Architects, was a corresponding member of the Institute of France, and the recipient quite recently of the Royal Gold Medal of the Royal Institute of British Architects.

IT is reported that in Duluth, recently, lumber dealers threatened to boycott any builder or architect who should specify Washington fir in any public buildings. The purpose, doubtless, was to make it necessary that home timber should be used. So far as lumber is concerned, it is almost impossible to talk of excluding any particular class of lumber from any particular district or country. No article of merchandise is so thoroughly cosmopolitan in its character as lumber, and the trade is becoming more so every year. Washington fir, or what is known in this country as the Douglas fir of British Columbia, is especially suited for certain work, and the world over, those who want the best lumber for shipbuilding, and in other cases where great strength and endurance are required, will be obliged to secure Douglas fir. In the Transactions of American Civil Engineers is published the following tests of woods: White pine broke at 3,872 pounds, all same sizes. Norway pine broke at 4,008 pounds, all same sizes. Douglas fir broke at 6,214 pounds, all same sizes. In other words Douglas fir was shown to be by a large percentage stronger than the strongest woods. This wood is becoming well known lately in its uses for bridges and other public undertakings. Some unusually large pieces have been sent east to Montreal to be used for dredger work there.

THE Montreal Masters Plumbers' Association have recently issued a circular to the trade, calling attention to the unsatisfactory conditions which prevail in the business as the result of master plumbers purchasing direct from the manufacturers instead of from wholesale dealers and jobbers, and the manufacturers and dealers selling direct to the general public. As a means of bringing about a more satisfactory state of things, the trade are asked to conduct business in future on the lines laid down by the resolution on this subject, adopted recently by the National Plumbers' Association of the United States, known as the Baltimore Resolution.

A VISIT to the site of the new Simpson building, at the corner of Queen and Yonge Sts., Toronto, serves to impress one with the change which has taken place in the methods and materials employed in the erection of large buildings. This building will rest almost entirely on iron supports. Even if the footings, on which rest the supports, are of iron, instead of stone, as heretofore, wood, stone and brick will be conspicuous by their absence, at least in the exterior of the building. In looking at the many tons of structural iron assembled for use in this building, the writer was led to remark that as the result of the change from stone, brick and wood, to iron construction, manufacturers of structural iron must be reaping handsome profits. The architect to whom this remark was addressed replied that such was not the case, but that on the contrary the cutting of prices amongst manufacturers and dealers in this material had apparently been carried to an extent which left but little room for profit.

DEFECTIVE construction of chimneys has not a little to do with the unsatisfactory working of heating furnaces, and as a rule, fault is laid at the door of the furnace manufacturer instead of being placed at the designer or builder of the chimney with which the furnace is connected. The two faults most commonly found in chimneys are, interior irregularity and flues of too small diameter. It is surprising what a large proportion of chimneys are defective in these particulars, and as a consequence hundreds of tons of fuel are being consumed every year to no purpose. Thus the builder of a chimney who aims by putting in a small flue, to save a few dollars on the cost of construction, thereby entails upon the occupant of the home a large unnecessary yearly expenditure for wasted fuel, and injures the reputation of the manufacturer who supplies the heating system. Architects should take notice of this matter, and see that chimney flues are sufficiently large and that they are carried up straight from bottom to top of the building.

THE Management Committee of the Public School Board of Toronto have under consideration the question of manual training. It is proposed that the forenoon of the last day of each week be set apart for the special study of subjects and designs in this branch ; that the scholars have worked assigned to them suitable for their capacity ; and that courteous discussion over their work be permitted the pupils during their exercises. The subjects included under this head are : Drawing, modeling in clay, plaster, cardboard, wood, cloth, metal or any other suitable material. An not unfrequent complaint against the school curriculum of the present day is that it covers too wide a field, and that pupils are being over educated in a direction that will render them little practical help in after life. To some extent, at least, there would seem to be reason in this charge. Where the future of the pupil is likely to run along professional lines it is important that there should be a breadth and comprehensiveness in the subjects studied. It is doubtful whether the man or woman, who will follow any of the leading professions, will not find help in almost any of the branches of study on the time table of the public and high schools of to-day. It is a different matter, when it will become necessary, either from choice or necessity, for the pupil to take up, what is sometimes termed, the more practical lines of work. And in the case of a large percentage of the pupils who attend the public schools it may be expected that they will, from natural bent, as the children of those engaged in mechanical pursuits, follow in these lines ; and where the professions are so terribly over-crowded we do not know but what this would be a wise course for others to pursue. Here the plan proposed by the School Board Management Committee would be exceedingly helpful, and if the success that has attended the schools of technology in Toronto and other places in Canada, Great Britain and the United States is to be taken as a criterion there is good reason to suppose that the School Board are following along a line that would not alone be popular but productive of the most satisfactory results.

MANUFACTURERS of furnaces, radiators and heating supplies are said to be considering the advisability of increasing prices, in view of the heavy advances which have recently taken place in the price of raw material. As an illustration of how prices have advanced, it may be mentioned that within a very short period the price of pig iron advanced $3 per ton, and within a period of one month, manufacturers were notified of five successive increases in price of iron pipe. Galvanized iron is another article used in the construction of furnaces, the price of which has advanced fully 30 per cent. It is difficult to see how manufacturers can continue to sell at old prices under these greatly changed conditions. It is a well known fact, that last year the iron producing establishments sold material at a loss, and this led to a corresponding reduction by manufacturers. Now these conditions are entirely reversed, so far as the far mills are concerned ; instead of shutting down operations during the summer, as they have been accustomed to do, they find it necessary to run full time and over time, in order to meet the demands, stocks having been almost exhausted at the commencement of the present year. The sudden and large increase in the demands, and the impression which has got abroad that prices are on the up-grade, has created a sort of panicky feeling among buyers, which has resulted in forcing prices up to a point which possibly may not be long maintained.

SEVERAL protests have appeared in the London Timber Trades Journal—one by Mr. Carl Zeidler, recently of Toronto Junction, whose firm carried out the contract for interior woodwork in the Ontario legislative buildings—against the action of the architect for the new legislative building at Victoria, B. C., in awarding to a Chicago firm a large contract for oak lumber. Mr. Zeidler states that the specifications for the Toronto buildings called for Canadian lumber, just enough foreign timber being used to make a contrast, and adds that Canada has enough of its own timber to make the finest interior wood work without going out of the country. The Timber Trades Journal, in commenting on the matter, says : "There is as much sense in bringing oak from the east to use in any kind of a building on this coast, as there would be in bringing salt water from the Atlantic to Puget Sound to bathe in. Tacoma, Seattle and Portland have each paid heavily for imported stock to finish buildings that could as well have been completed with native lumber." Without professing to know anything about the circumstances of the present case, we are strong advocates of the use by Canadian architects of native materials, wherever these are to be had approaching in fitness and quality imported materials. On the same principle that Canadian architects object to commissions being given to foreign architects for the erection of buildings in Canada, the specifying of foreign materials in preference to native material by Canadian architects is an injustice.

TRADE IN WOOD-WORKING LINES.

A STUDY of the figures contained in the report of the Department of Trades and Commerce, for the fiscal year ended June 30th, 1894, now published, furnishes some suggestive thoughts as to the possibilities of extending Canadian trade in wood-working lines.

The export trade in doors, sashes and blinds during the past five years has grown at a satisfactory rate, the business for 1894 being more than double that of 1890. The figures are as follows : 1894, $158,196 ; 1893, $130,349 ; 1892, $123,144 ; 1891, $86,450 ; 1890, $60,474. Let this increase continue in the same proportion for another five years, or why not at a greater ratio, and the trade will have assumed a very considerable size.

The difficult matter in building up an export trade is to obtain entry into foreign markets, but having done this then time will establish the merits of the goods imported. Furthermore, it take some years for manufacturers to ascertain what class of goods particular localities require, and this now done, the business in doors, sashes and blinds of Canadian manufacture ought

to grow apace. It is unnecessary to remark that no goods in these lines are imported into Canada, shnwing that the home goods are of a class that meet fully the requirements of our people, even those who may be deemed specially fastidious in their tastes, or who consider it the proper thing to look abroad for what is wanted.

If reference is made to the trade in mouldings it will be learned that the exports in this direction have since 1891 grown largely. The figures are : 1894, $36,558 ; 1893, $23,164 ; 1892, $7,083 ; 1891, $5,153. There was imported during 1891, mouldings to the value of $31,745.

THE NEW COURT HOUSE ROOF.

WORK on the new Toronto Court House will be sufficiently advanced before the close of the year to permit of covering in, and the question now is, shall it have an iron roof? The matter came before the Property Committee of the City Council a week ago, and has given rise to considerable newspaper discussion since then. At the committee meeting Ald. Dunn objected to an iron roof on the ground that it provides no absolute security from fire in a building full of wood. This view has found expression in several newspaper communications. Is the objection well founded ?

Architect Lennox, who, as might be expected, has given a good deal of study to the question, favors an iron roof. He argues that with a building costing one and a half millon dollars, it would be poor economy to cover it with a roof of the ordinary kind. In his judgment, and experience, there is no doubt about the fire protection an iron roof affords. It must be remembered that the Court House roof will be about 1,400 feet around, and from 50 to 70 feet wide, and towering as high as this building does, it would be a ready target, in case of fire, not only from the buildings immediately surrounding it, but from fire even some reasonable distance away. In the case of some of the worst fires that have occurred in the city and elsewhere these have resulted through flying embers lighting on an inflammable roof, or finding their way through inflammable material surrounding the roof. Because Knox Church steeple was covered with metal the argument was that it could not catch fire and yet a flying ember from the Simpson building found entrance somewhere and fire was started.

One newspaper correspondent has stated that a fire starting in the building would work its way up to the roof, and then by the immense heat the iron would become warped or melted. If the building were one immense furnace, as it were, with no means of egress for the flames this might be the case, but separated by brick partitions and no lack of windows it is hardly possible that a fire could get under way to the extent suggested. It is also urged that the immense weight of the falling iron would bring down the walls with it to the extent that it would do them tremendous damage, so that not only would the roof be lost, but to a large extent the walls also. The writer of the letter containing this sentence may be a "Taxpayer," as he signs himself, but he can hardly have a practical knowledge of building. The view is not alone that of Mr. Lennox, but is very generally endorsed by architects, that the effect of the falling of the iron roof would be to go down and it would really serve as a means of burying and extinguishing the fire.

Experience in the erection of buildings of a similar character, though in many cases not involving nearly so large an investment, is emphatically in favor of an iron roof. The best public buildings, and those of a semi-public character belonging to monetary and kindred institutions throughout the United States, have the protection of an iron roof. The Freehold Loan Building, on the corner of Victoria and Adelaide Sts., Toronto, constructed under the superintendence of Mr. Lennox and costing less than three hundred thousand dollars, has an iron roof and is absolutely fire proof. The view of Canadian architects is almost generally with Mr. Lennox. To quote the language of one of the most prominent in Toronto, when spoken to about this matter : "The placing of an iron roof on the Court House would add nearly 75 per cent. to the fire protection."

The additional cost of an iron roof is the main, apparently, if not the only substantial, argument that has been employed. It seems, however, to be forgotten that it might be the worst of economy to expend the large amount of money that the new Court House will cost, and then for the sake of perhaps forty thousand dollars additional, place the entire investment in serious jeopardy. The Court House is not built for to-day, but practically for all time, and every precaution necessary, and that experience would suggest, ought to be exercised to make it a building that may last for all time by being protected from every possible risk, and especially that of fire.

ROOFING TILES.

AMONG builders, certain technical names have been applied to different kinds of tiles, most of these names being derived from the shapes.

Plain or crown tiles are such as have a rectangular form and plane surface. In England a statute provides that they shall be 10½ in. long, 6¼ in. broad, and ⅝ in. thick, and are manufactured with two holes in them, through which, by means of oak pins, they hang upon the laths. In use one tile laps over another, or is placed over the upper part of the one immediately below ; that part of the tile which then appears uncovered is called the gauge of the tiling. The so-called Italian tiles differ somewhat from these, as, instead of being flat, they are slightly curved, fit easily one into the other, with a horizontal indentation across the upper part, to prevent the wind drifting the rain over the tile head ; they have either wide or narrow vertical rolls.

White glazed tiles are used for lining the walls where reflected light is needed.

Three courses of plain tiles laid in cement and well bonded have been for many years employed for slightly curved roofs to form terraces, roofs for cellars under paving, as roofs over small back building, and for similar purposes. It has been asserted that the tiles should not be covered with cement. Portland or other cement laid on brick arches, or on tile, or on a flat concrete roof, supported by iron joists, also asphalted roofs, all generally cracked and let in wet, especially when there is any traffic on them, or their foundations are not perfectly stable. In England tarred roofing is formed of plain tiles in three courses rendered on the top to the thickness in all of about 4 in., carried over by arches slightly cumbered, spring from small brick piers, and tied by light iron rods, which form their cord line. These flats have an immense weight upon them, and are cast in one piece, as it were, there being no perceptible joint ; they are completely water-tight, and can be easily cleaned.

Plain tiles are laid on different gauges ; 210 plain tiles, laid flat, will cover a square of tiling. Pan tiles are generally pointed in mortar, which, if it be not very strong, will not stick ; in consequence of this the roofs require fresh pointing every few years, especially in exposed situations. Many tilers have a practice, when plain tiles are set in mortar, not to peg more than about one hole in ten. This is bad practice, as, with the decay of the mortar, the tile will slip down. In some parts of the country the ancient custom prevails to bed the tile in hay or moss, and when the roof is of the full pitch, this suffices without mortar. They may even then be laid dry. But with any less pitch some precaution must be used to keep out drifting snow, and such wet as may be blown up between the tiles, lifted by the force of the wind. In lieu of oak pegs, extra large flat-headed wrought nails, made of pure zinc or of zinc and copper, have been used, and it has the advantage of allowing a tile to be replaced from the inside of the roof by lifting up the others to place in the tile and drop in the nails in a few seconds.

Pan tiling is laid to a 10 in. gauge, and 180 pan tiles will cover a square.

Glass tiles have been used on roofs where a small modicum of light is required.

Tiling is measured by the square of 100 superficial feet ; a square will require 800 at a 6 in. gauge, 700 at a 7 in. gauge, and 600 at an 8 in. gauge. The gauge necessarily regulates the distances of the laths, and at the same time must be dependent on the slope of the roof, which, if flat, should not be less than 6 in., as, for instance, above the kerb in a kerb roof, and not more than 8 in. in any case. A square of plain tiling requires about on an average a bundle of laths, two bushels of lime and five of sand, and at least a peck of oak pins. A bundle of laths 3 ft. long contains 160 ; 4 ft., 120, and the 5 ft., 100. The nails used are fourpenny. A square of pan tiling requires 180 tiles laid at a 10 in. gauge.—Illustrated Carpenter and Builder.

COPY OF ORIGINAL DRAWING FOR THE ROOF OF UNIVERSITY CONVOCATION HALL, TORONTO, SUBMITTED IN THE O. A. A. EXAMINATIONS BY MELVILLE P. WHITE, TORONTO.

ENTRANCE TO A HOUSE—ERNEST WILBY, ARCHITECT, BUFFALO, N. Y.

NEW LIBRARY BUILDING, McGILL UNIVERSITY, MONTREAL.—A. T. TAYLOR, F.R.I.B.A., ARCHITECT.

Several exterior and interior views of the new library building in connection with McGill University, Montreal, are presented in this number. The building is one of many gifts presented to the university by Mr. Peter Redpath. The foundations were laid in the spring of 1892, and the completed structu e formally opened by their Excellencies the Governor-General of Canada and Countess of Aberdeen, on the 31st of October, 1893.

The construction is as nearly fire-proof as possible, and the stack room is entirely so. The whole of the main floor is of steel beams and porous terra cotta arching. The other floors and the roofs, where not of this material, are of solid oak beams, and flooring on the slow combustion principle. The stairs are of iron and slate. Externally, the building is constructed of the Montreal limestone, of a whity-grey color in dressed ashlar work, except the basement, which is of rock-faced ashlar. The roofs are of blue Rockland slates and copper. The doors are of polished oak with wrought-iron grille work and fittings. The style adopted is a free treatment of Romanesque, which lends itself to the requirements of such a building, as being at once dignified and yet picturesque. The tower rises to a height of about 90 feet. The salient points of the design are accentuated by stone carving, embracing suitable subjects such as the symbolic figures of the four Evangelists, the College arms, the crest and motto of the donor of the Library. Convenience of arrangement and suitability for its purpose, combined with substantiality and solidity of construction, were the desiderata; afterwards came in the elements of beauty, proportion and grace, in some measure all of which have been attained without the sacrifice of one to the other.

STACK ROOM, NEW LIBRARY, McGILL COLLEGE, MONTREAL.

After much consideration, the architect adopted the "stack" system as the best arrangement for the books. Stacks were selected of the "Library Bureau" type, with uprights of grooved steel, in which bracket ends slide up and down, being fixed at the required height by a wedge easily adjustable. The pattern of the bracket ends was specially made for this library; the shelving is of polished oak. This stack room has four storeys, with straight stairs, and a lift for books; on each storey there is a wide bay window, back and front, for special privileged readers, where they can consult any of the books on the spot, and not obstruct the passage ways between the books. In the future, when the stack room requires to be enlarged, these bays will form the centre of the stack, and the accommodation will be thus nearly doubled.

In the basement or lower floor, which is entirely above ground with the exception of a small portion on one side, five studies or seminary rooms are arranged for special studies, fitted up with tables, chairs, and book-cases for books bearing upon these special subjects. These can be reached by a separate door from the campus, or by the main entrance. At the other end of the building is a wide entrance for the reception of boxes of books, which opens into the unpacking room. From here the books are then taken to the cataloguing room immediately above, by a lift in a small projecting wing in which also a staircase is arranged, for the exclusive use of the librarians. The rest of this floor is occupied by the caretaker's house, lavatories, heating chambers and coals.

On the main floor the principal feature is the great reading room, 110 feet long, 43 feet wide, and 44 feet high to the top of inner roof, with a high open timber roof having the hammer beams ornamented by carved heads of grotesque animals. At the further corners are lofty oriel windows with seats round same. In the centre of the S. E. side is a recessed fireplace or inglenook, with a red stone mantel inside, having the following motto cut in relief in a panel: "Cease not to learn until thou cease to live." At the entrance to the inglenook is a large massive carved oak mantel-piece about 14 feet high, with the following quotation from the Proverbs, cut on the carved frieze: "Happy is the man that findeth wisdom, and the man that getteth understanding." On the opposite side of the reading room is a lofty square recessed window with seats round. A large wide level gallery has been arranged at one end, which may be used for the display of rare illuminated books, manuscripts and missals in glass cases, and other purposes, and from which visitors can obtain a good view of the reading room, without disturbing the readers. Below this gallery, the Librarian's room and the cataloguing room are obtained, divided by an ornamental glass screen from the reading room. This is the working department of the building, where all the books are catalogued and arranged; contiguous to this is the attendant's counter for the distribution of books, and from this is the entrance to the stack room already referred to, protected by steel fire-proof doors. Between the cataloguing room and the reading room are placed the Card Catalogue cases, opening on both sides, so that the cards may be placed in the drawers from the one side, and consulted by the readers from the other. The remainder of this floor is taken up by a well-lit room for periodicals, and by cloak-rooms. In the tower is placed the staircase, opening into the entrance hall and into the reading room by ornamental arches. The vestibule and entrance hall have marble and oak dados respectively, and both have marble mosaic floors. There is also a special Muniment vault for the care of precious books and muniments. On the upper floor, in addition to the gallery, are a Professors' room, and a large room or hall with a high ceiling for architectural casts, sculpture, etc. The fittings of the reading room are all of oak, of a substantial character and polished, the tables being arranged across the room so as to have the light right and left. Round the walls are arranged

book cases for reference books. The windows are glazed with leaded lights in geometrical patterns, having panels in same for quotations and inscriptions. It is the intention to have all these panels filled in with suitable mottoes painted on the glass as soon as a selection can be made. At present only a few have been painted on in the vestibule, entrance hall and staircase.

ENTRANCE HALL AND STAIRCASE, NEW LIBRARY, McGILL COLLEGE, MONTREAL.

Special attention has been given to the three-light windows facing the campus, and to the five-light window at the other end of the reading room. These have been filled in with beautiful painted glass, the gift of Mrs. Peter Redpath. The three light window is specially elaborate, having a number of groups of the men great in art, poetry and music. The five-light window is not so elaborate as the other, and the colors were purposely kept lighter, so as to obstruct the light as little as possible. These windows are respectively dedicated to law, history, philosophy, astronomy, medicine, and have medallion portraits of the great masters in each subject.

For artificial light, electric lamps are used entirely, and in addition to handsome polished antique-brass electroliers suspended by chains from the roof, the reading room is lit by standards, with green shades, placed on each table. The walls of the reading room are colored a soft shade of green, relieved with gold, so as to be restful to the eye, and yet not too absorbous of light. The walls of the entrance hall and staircase are colored a dull soft red. All the floors are covered with cork carpentering to deaden the sound. The heating is entirely by hot water on the direct radiation system.

MORTAR.

It was found by Berthier after an analysis that Roman cement is composed of carbonate lime 657, carbonate magnesia ·005, carbonate iron ·063, carbonate manganese ·019, clay silica ·180, clay alumina ·066, water ·013. Berthier considered that with one part of common plastic clay, and two and a half of chalk by weight, a very good hydraulic lime could be made, which would set as speedily as the English one; but it is not probable, he allows, that we can obtain by mixtures hydraulic lime which will acquire as great hardness and solidity as the natural mortar, because these qualities depend, not only on the composition, but also on the state of compactness. The greater density the material possesses, and if it slake without changing its volume, the greater facility will its particles have in becoming aggregated, and the less shrinking will there be during its consolidation. Berthier drew the following conclusions from a numerous set of experiments. A limestone which contains 6 per cent. of clay affords a lime already perceptibly hydraulic. When the lime amounts to from 15 to 20 per cent., it is very hydraulic, and when from 25 to 30, it sets almost instantly, and may therefore be considered as Roman cement. He conceives that the iron and manganese have no effect whatever in occasioning the hardening. In a mortar which owes its solidity to the adhesion of the lime to the alloys, or substances with which it is mixed, there is evidently an advantage in multiplying as much as possible the surfaces of contact. Thus alloys with large grains do not afford mortar so solid as the pulverulent ones, because there are spaces filled with pure lime which do not present the same resistance to fracture as the other parts. On the contrary, allovs in powder, though they present the greatest surface, yet require a very large proportion of lime. To obtain, then, with the smallest possible quantity of lime, mortars possessing the greatest solidity, alloys must be used containing particles of different sizes, avoiding always the mixture of argillaceous substances, which form a paste with water, but have no coherence. These opinions have been put to the test of experiment on a large scale, the sand usually employed in Paris affording a better mortar when merely washed than when the fine particles are removed by a sieve.

BLACK BIRCH FOR INSIDE FINISH.

BLACK birch for doors, wainscoting, and other interior work, is being introduced to a considerable extent, and is certainly one of the handsomest of the many varieties of woods that are being introduced into new houses, while the cost is much less.

Black birch is a close-grained wood, and is as easy to work as walnut, and is much cheaper than either walnut or cherry. There is a great difference in the quality and color of birch, that growing upon high and dry land being hard and susceptible of good polish, while the growth on swampy land is soft, and therefore not well suited for the purposes the upland product so admirably fills.

Birch grows in our northern latitude, and the trees attain considerable height and size in localities, and there is a species of bird's-eye birch which is well calculated for furniture. It resembles bird's-eye maple, and when polished it possesses that sheen which renders satinwood so pleasing to the eye. We predict for black birch an important place among the fancy woods for house finishing and furniture.

FIRE-PLACE AND MANTEL IN READING ROOM, NEW LIBRARY, McGILL COLLEGE, MONTREAL.

A convent to cost about $42,000 is now in course of erection in the parish of St. Louis de France, Montreal, at the corner of Cadieux and Roy streets. The building will be of brick and stone, two storeys, with mansard roof and basement.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

THE AUGE BILL AS AFFECTING BUILDERS.

The amendments commonly known as the Augé Bill affecting that section of our civil code concerning builders and others engaged in the building trades, interest in such a degree the readers of this journal that it is probably opportune to say a few words about it. Mr. W. A. Baker, advocate, in a very able article in a recent issue of "La Revue Legale," exposes the situation in its true light and suggests several amendments, the principal of which are the restoration of the "proces-verbaux," and a restoration of the redemption system under the Augé Bill.

Article 2013 of the civil code as it existed before the late amendments, gave privileges on immovables to builders or other workmen, and architects, over the vendor and all other creditors upon the additional value given to their immovables by their works, provided an official statement (proces verbal) establishing the state of the premises previous on which the works were to be made, had been previously made by an expert appointed by a judge of the superior court in that district, and that within six months from the completion of such works have been accepted and received by an expert appointed in the same manner, which acceptance and reception were established by another official statement containing also a valuation of the work done. In this manner builders or workmen and architects were privileged to the amount of valuation ascertained by the above said second statement, and was reducible to the amount of the additional value which the immovables had at the time of the sale.

Article 2013 is now changed to read as follows:—"The laborer workman, furnisher of building materials and the builder (principal contractor) have on the immovables a right of preference to the amount of additional value given to the estate by works or materials furnished, etc."

As it will be noticed, the architect is excluded amongst the privileged and takes rank amongst other creditors. What is the reason for excluding him? Does he not contribute to create the additional value of the estate as much as the builder or any one else. And as to the supplier of materials, he certainly ought to come under the clause regulating traders and the general commerce, as if he sells to a contractor and has any doubt as to his responsibility, he has but to require of him the payment of his goods c. o. d., as is done in other lines of trade. The right of preference or privilege exists in the following manner: During the whole time that the work last, and with registration if effected within 30 days of the completion of the work, but for a period not exceeding two years unless there are arrangements to the contrary stipulated in the contract or a judgment to that effect. The conservation of the privilege is subject to the following conditions: The laborer and workman have to inform the proprietor in writing, or verbally, before a witness at every term of payment due them, that they have not been paid, and the furnisher of materials declare to the proprietor the contracts passed between the contractor and himself for materials, before they are delivered, and also their cost. The sub-contractor shall also declare to the proprietor the contracts made between himself and the principal contractor. What is the meaning of this clause? It is the most obscure in the bill. If it is deemed necessary to declare to the proprietor the contracts he closes with the principal contractor, is it that he has a right of preference or a privilege? It is not probable, as article 2013 ignores entirely the sub-contractor and mentions as privileged only the laborer, workman, supplier of materials and the principal contractor. It is a mere mine of exploitation for lawyers, as it is almost impossible to foresee the result of a law-suit based on this cause.

Another source of law suits in the Augé Bill is that there are no longer any "proces-verbaux." It would be well to advise those engaged in the creation of the additional value, to make use of the "proces-verbaux" as in the past, but with this difference that each of the two interested parties should appoint an expert to guard their interests, as it is the best means of protection for all, and the foundation of the privileged credit.

In his article Mr. Baker concludes by saying that what prevents the Augé Bill from working is that all the accessories indispensable for its proper working have been ignored, and suggests that the sale by right of redemption be restored by an amendment to its former popularity, as according to him the right of redemption is an indispensable accessory for the security of the loaner who by the transaction has all the privileges of a proprietor, and has a right to the notices of the Augé Bill, and can therefore keep an eye on the transactions between the proprietor and the contractor. The falling into desuetude of this system is to be attributed to an amendment made a few years ago which declares that if the seller fails to bring a suit for the enforcement of his right of redemption within the stipulated term, the buyer remains absolute owner of the property. This scares all speculators, as for unforeseen causes they might not have realized the cash wanted at the required period and therefore lose all their rights.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The semi-annual examinations announced for the 25th, 26th and 27th July, were held as announced in the rooms of the association, but lasted only two days, the 25th and 26th, there being no candidates for the diploma. Four candidates presented themselves for matriculation examinations, all of which passed in the following order of merit:—1st. F. Dubreuil; 2nd. L. A. Venne; 3rd. L. Lionnais; 4th. J. L. Morin. The examiners were Messrs. A. C. Hutchison, 1st vice-president, A. T. Taylor, 2nd vice-president, and J. Venne, secretary.

MASTER PLUMBERS' ASSOCIATION.

The Montreal Master Plumbers' Association have petitioned the City Council to permit the use of tile drain pipe in certain cases, which is now forbidden by the drainage by-law inside of houses from two feet of outside of exterior stone foundation wall. The Association of Architects in revising the building by-law have attached a drainage and ventilation by-law to it, and have confirmed the existing by-law. It is thought that the Board of Health, to whom the matter has been referred, will not alter the present state of affairs, as the use of cast iron pipe is recognized the best, and is being now more extensively used than ever in large cities.

Montreal importers of drain pipe are about to make and organize a more suitable appraisement of this class of goods by the Customs Department, individual efforts in this direction not having met with success. The importers claim that the arbitrary basis upon which the duty is levied at present was adopted at a time when abnormal prices obtained in the European market as the result of the great coal strike a few years ago, and that consequently the standard of valuation does not correspond in any way to prevailing values. A prominent dealer whom I interviewed said: "Mr. Douglas, the appraiser, examined two or three dealers in this city, but the enquete came abruptly to an end for unknown reasons. The arbitrary scale on which the prices are based are about double to what is being paid for the material. Invoices shown by manufacturers in Scotland are shown to Customs officials here, but are not accepted."

PERSONAL.

Mr. W. H. Carrick, manager of the Gurney Foundry Co., Toronto, accompanied by Mrs. Carrick, sailed a fortnight ago for Europe on a pleasure tour.

We regret to announce the death from paralysis, of Mr. Wm. Elliott, of the firm of Elliott & Son, wall papers and stained glass, Toronto. The sad event occurred at his residence on Sherbourne St. about the middle of July. He was born in Ireland in 1829, and came to Canada when a boy, locating in Toronto, where he has been in business for nearly forty-five years.

We are pleased to learn that the enterprise displayed by Mr. J. A. Pearson, of the firm of Darling, Sproatt & Pearson, architects, Toronto, in opening an office and taking up his residence for about two years in St. Johns, Nfld., immediately following the great conflagration in that city, has brought him large reward, not only in the shape of commissions, but in the form of one of the fair daughters of the ancient colony, whom he has recently brought home as his bride. Regardless of the opinion of the majority, there is a minority who believe that the great St. Johns fire was a most fortunate occurrence, it being the means of introducing to one individual both a new-found-land and a new-found-happiness. May the latter continue as long as the former.

The firm of Arnoldi & Calderon, architects, Ottawa, has been dissolved, Mrs. Calderon continuing for the present.

The Toronto Steel Clad Bath and Metal Co. have published in pamphlet form a number of excellent testimonials from architects and others as to the merits of their steel clad baths.

The idea that ten cents for the Cosmopolitan means inferiority from a literary point of view is dispelled by the appearance in the August number of such writers as Sir Lewis Morris, Sir Edwin Arnold, Edgar Fawcett, Tabb, W. Clark Russell, Lang, Sarcey, Zangwill, Agnes Replier, etc.

STUDENTS' DEPARTMENT.

PHOTOGRAPHY IN NATURAL COLORS.

A. AND L. LUMIERE point out that the indirect method of photographing in natural colors has not received a proper practical application, because of the difficulty experienced in selecting the colors, and in preparing and superposing the monochromes. They recommended the use of orange, green and violet screens for preparing three series of negatives presenting a maximum of sensibility to the rays which the respective screens allow to pass. Specimens of photographs so prepared were exhibited before the Paris Academy of Sciences. The printing and superposition of the monochromes have been successfully accomplished by employing birchromated gelatine to which are added substances insoluble under certain conditions. If, for example, five per cent. of ammonium bichromate, and five to ten per cent. of silver bromide in the form of emulsion, be added to a ten per cent. solution of gelatine, and the preparation be spread in a thin layer upon a plate of glass, a surface is obtained which can be exposed under a negative, and will reproduce the picture by the action of light. After exposure, the plate is washed with cold water, and the portion of the film acted upon by light being rendered insoluble, remains and serves to print the image form on the application of suitable colors. The silver bromide, which, by the way, may be replaced by other insoluble precipitates, is easily removed by the action of sodium hyposulphite, and proofs can then be printed from the plate in any color, showing all the graduations of tint present in the negative. Polychrome prints may be obtained by receiving on the same plate monochrome red, yellow, and blue images successfully, by means of three corresponding negatives, and isolating each image from the preceding one by an impervious layer of collodion. By employing dyes of greater or less concentration, or by simple decoloration with water, variation in the relative intensity of the monochromes is readily obtained.

USEFUL HINTS.

A GIVEN number of feet of radiating surface properly placed, will be found more effective than a greater amount located to save floor space or be out of the way.

CHLORIDE of zinc paint, although virtually a water-color, dries quickly and hard, so that it can be washed with soap and water when necessary, and will be found a preservative of wood, rendering it almost incombustible.

WIRE nails for joining dressed boards or barrel heads by being driven into the different edges, will be made by machinery and the price greatly reduced. This will dispense with the use of the brace and bit and wedge-plug for that use.

FOR filling up the pores of the wood before commencing to polish: For white wood, equal proportions of whiting and plaster of Paris, thinned to a paste with turpentine and well into the grain of the wood; for mahogany, add rose pink, or whatever the color of the wood is, and dry color to match up to same.

A NOVEL engineering scheme in the construction of a foundation we have heard of is the one recently used in New York—to freeze a bed of quicksand which impeded the work. A row of 4-inch pipes was sunk to a depth of 40 feet. These pipes were capped at the bottom, and contained inside similar pipes opened at the bottom. From a large condenser cold air was forced through these smaller pipes into the larger, from which it returned to the condenser. The air was cooled to a temperature of about 45 deg., thus freezing the surrounding mud and wet sand, and checking their flow into the excavations.

WE have long had slag paint and pavement, but the latest is a slag brick chimney. According to L'Industrie, this plan was adopted by the Courrieres and Ortricourt companies, and their example is followed by the works of Arbel and Douai. The latter establishment planned a chimney 164 ft. high, and to weigh but 379 gross tons, about half the weight of a brick chimney of the same dimensions. A special cement was to be used which would bind together the blocks composing the chimneys so firmly as to require no chain or iron band for strengthening. This is an interesting application of a cheap industrial by-product, which, should the experiment prove a success, will be appreciated by metallurgists.

THE scientific journals describe a series of tests lately made to determine the loss of heat from steam pipes due to radiation, three distinct conditions being observed in the calculations, namely, bare pipes, pipes covered with 1 inch of composition, and pipes over-laid with 1 inch of composition and three surfaces of hair felt, each ½ an inch in thickness. The steam pressure used was from 45 to 60 pounds, and the result showed that with 1 inch of composition out of a possible loss of 100 per cent., 83½ per cent. was saved, and with the extra felt covering, 8¼ per cent. additional marked the saving. It is marked that if a single pound of coal is required to evaporate 8 pounds of water into steam at 60 pounds pressure, then six and a half hundredweight of coal would be needed every year to make good the loss of heat for every square foot of uncovered steam pipe.

PROCESS OF GALVANIC BRONZING.—By means of a recent French improvement, the process of galvanic bronzing is said to have been made not only more simple, but capable also of giving every tone, from that of barbedian bronze to antique green, governed by the length of time that the copper is allowed to remain in contact with the liquid; after the piece has been well scoured, it is covered by means of a brush with a mixture composed of twenty parts of castor oil, eighty of alcohol, and forty parts each of soft soap and water. Thus treated, the piece left to itself for a period of twenty-four hours becomes bronzed, and if the duration of contact be prolonged, the tone changes, a very great variety of tones, pleasing in their appearance, being obtainable in this manner. The drying is finally effected with hot sawdust, the only remaining operation being then that of coating the piece with colorless varnish largely diluted with alcohol, thus insuring work of the finest character.

PRESERVING WOOD BY LIME.—On the preservation of wood, a Canadian experimenter writes: "I have for many years been in the habit of preparing home-grown timber of the inferior sort of fit, Scotch spruce and silver, by steeping it in a tank, or a hole dug in clay or peat, which was fairly watertight, in a saturated solution of lime. Its effect on the sapwood is so to harden it and fill up its pores that it perfectly resists the attack of the little wood-boring beetle, and makes it, in fact, equally as durable as the made wood. I had a mill which was lofted with Scotch fir prepared in this way in 1850, and it is in perfect preservation. The timber is packed as closely as it will lie in the tank, water is let in, and unslaked lime is thrown on the top and well stirred about. There is no danger that the solution will not find its way to everything in the tank. I leave the wood in the solution for two or three months, by which time an inch board will be fully permeated by it. Joists and beams would, of course, take a longer time for saturation; but in practice we find that the protection afforded by two or three months' steeping is sufficient, if the scantlings are cut to the sizes at which they are to be used."

WEATHERING OF NAILS.—Mr. Samuel Cabot writes as follows to the American Architect:—When a plain iron nail in any structural woodwork is so placed that water can gradually work between the nail and the wood, a hydrated peroxide of iron is formed by the oxidation of the surface of the nail. This oxide acts rapidly and very destructively upon the fibre of the wood, which in chemical parlance is almost wholly cellulose, the same material which we find in cotton and linen. The action of this hydrate upon the cellulose, seems to be a completely destructive one, resulting finally, in the case of a nail, in its becoming so loose in its place that it can be frequently removed with the fingers, as you draw a pin from a cushion. If the examination is then made, all the adjacent parts of the wood will be found to be deeply tinged with the red-brown color of the hydrate of iron, and to be completely disintegrated and decayed by the oxidizing effect of the hydrated iron oxide. This, of course, tends to gradually diminish the structural strength of the part so effected, and in such cases, for instance, as piazza rails and posts, may result in dangerous fickle support and so in perhaps serious accident. Of course, the means of avoiding these objections are quite obvious: The first is to shun, as far as possible, the exposure of the nail head or point in a position where water can trickle upon it and follow down between the nail and the wood; but a still more radical, though more expensive cure, is the use of galvanized nails, or still better, composition nails, in all such cases, and it is the writer's conviction that such construction would be a great economy in all cases such as above cited. If any of your readers will carefully observe the conditions that obtain in such cases, they will need no better testimony than their own eyes.

CEMENT AS A SAFE MATERIAL.—The Improvement Bulletin gives the following interesting test of the fire-proof and non-heating conducting qualities of cement: A safe constructed of cement, with steel wire netting placed in between, was tested by order of the Reichsbanks, the German Government's banking establishment. The question to be decided was whether it is practical to build vaults of this material for safety against fire. A safe was placed upon a pyre of logs drenched with kerosene, which, after being set on fire, kept the safe for half an hour exposed to a heat of about 1,800 degrees Fahrenheit; that is, a heat in which iron will melt. Two hours after the safe was opened and the contents—silk paper, draft blanks and a maximum thermometer—were found to be absolutely uninjured. The maximum thermometer showed that within the safe the temperature at no time during the test rose above 85 degrees. This seems to prove that cement safes within buglar-proof steel vaults fill all the requirements that can be possibly expected.

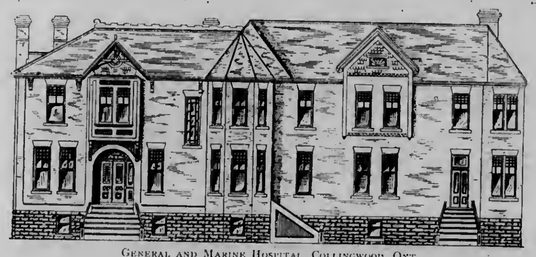
COLLINGWOOD GENERAL AND MARINE HOSPITAL.

By the munificence of Mrs. Lett, the Trustees have been enabled to erect a large addition to the Collingwood General and Marine Hospital. The new wing will contain upwards of twenty rooms, including wards, corridors, operating room, mortuary chamber, lavatories and offices, and will be fitted with a fair supply of modern hospital appliances.

The building has a frontage of eighty, and an average depth of forty feet; it is constructed of cream colored bricks on a rubble stone foundation, and is three stories high, including basement.

The whole building throughout is to be heated by steam and is to be fitted up for electric light, bells, etc. The kitchen, dining room, laundry, furnace room, buttery, vegetable cellar, and fuel rooms are in the basement, which is well lighted, airy and dry. All the wards, operating room and convalescents' parlors, are well ventilated.

The illustration shown herewith presents a front view of the building with the new wing added. When completed, this hospital will be one of the best equipped in the Dominion, outside the large cities, and in its own way will do an immense service to suffering humanity in this part of the country. The management of the institution is in the hands of a number of charitably disposed ladies of the town, to whom much credit is due for the efficient manner in which the hospital work in the past has been pursued. The generous gift of several thousands of dollars by Mrs. Lett, one of the most assiduous workers in behalf of the hospital, will extend the sphere of usefulness of the institution, and enable the management to still further diffuse its blessings.



General and Marine Hospital, Collingwood, Ont.

The new building will be ready to receive patients sometime this month (August), when an efficient staff of trained and experienced nurses will be retained for service if required.

The contractor for the building is Mr. John Peterman; the designs for the new work were prepared by Fred. T. Hodgson, architect, who is also supervising the work.

MOVING A STONE DWELLING.

A rather interesting piece of work in the way of moving a dwelling house was recently completed in the city of Brooklyn, N. Y., where an old stone mansion covering an area of 58×68 feet in size, and weighing about 1,300 tons, was carried a distance of about 50 feet and placed upon new foundations. The work was of such a nature, says Carpentry and Building, that many were skeptical as to its successful performance, but such progress has been made in late years in the methods of moving buildings that the structure was transferred without the development of any visible cracks in its walls. One of the difficulties encountered in the execution of this piece of work was the lack of solid side walls to the house, these being composed of rock faced ashlar with a backing of broken stone. There were also window openings on all four sides which had to be taken into consideration in the moving.

The first step was the cutting of a large number of openings in the stone foundation walls so as to admit the timbers which were to support the building and carry it to its destination. The blocking used was of spruce and yellow pine measuring 10×10 and 12×12 in cross section and cut in lengths of four feet each. This was arranged in position under the building, and by means of hydraulic jacks and screws the structure was lifted from its foundations. Immediately under the first tier of floor beams were placed 12×12 inch timbers, the ends of which pierced the front and rear walls. Under this tier of timber and at right angles to it was another tier of 14×14 inch pieces which pierced the two side walls, these two tiers of timber being the ones having an immediate bearing on the walls of the house. Under these was placed a tier of 14×14 inch timber to serve as sliding ways, these moving on 14×14 inch pieces placed upon the ground and extending in the direction of the new site of the building. These were known as "ground ways" or skids, and between them and the sliding ways lubricants were placed for the purpose of reducing friction to a minimum. When this had been done 10 screws were placed in position along the side of the house, one end of each screw abutting against a piece of heavy timber secured to the ground ways by means of heavy chains, while the opposite end of the screw worked in a hollow log called a "pump," which pressed against the timbers upon which the building rested. In moving the structure two men took position at each screw and upon a given signal by the foreman the screws were given a quarter turn. This was continued until the screws had been run out practically to the full length, when the chained pieces were moved forward and again made fast, the operation being continued until the building had been forced forward 20 feet. The bearings were then changed and the structure moved in a direction at right angles to the first for a distance of 30 feet. Such care was taken in the moving that one day was required for the 20 feet and nearly two days for the 30 feet. When the building had reached its destination 100 screws and 10 hydraulic jacks were placed under the timbers and the house raised to an elevation to correspond with its new foundations. The latter were left with openings to correspond with the position of the projecting timbers under the building, so that when it was lowered in place the blocking could be removed and the timbers easily withdrawn.

The work was done by B. C. Miller & Son, of Brooklyn, N. Y., who, our readers will recall, successfully moved the brick railroad station at Mott Haven, a description of which appeared in these columns some months ago. The scheme there employed was followed in all its essential features in the moving of the Brooklyn house.

Not far from this stone house was a frame building which was moved by the same concern in nearly a half circle, so as to change the front around and make it face on another street, running parallel with its original position. The work was done by laying the "ground ways" in such a way as to describe a semi-circle and employing capstans operated by horses instead of jack screws. The method of timbering was practically the same as in connection with the stone house, except that less material was required.

PRESERVATION OF WOOD FROM DECAY.

A special committee of the American Society of Civil Engineers, detailed to investigate the subject of the preservation of wood from decay, has spent four years in practical experiment and observation, besides inquiry into the experiments and conclusions of others extending over a period of more than thirty years. Their investigations included all the established methods of preservation, such as treatment with creosote, zinc salts, etc., and also with the products of petroleum. The latter have been claimed by many to be strong in preserving properties; and as they are very cheap, the substantiation of these claims was of special importance. Below are given some extracts from the report of this special committee, showing the conclusions deduced of the comparative value of petroleum products, and the best of the established methods:—

"Experiment proved that oil of tar, or creosote, was perhaps the most powerful coagulator of the albumen (of wood), while it, at the same time, furnished a waterproof covering for the fibre, and its antiseptic properties prevented putrefaction."

"There seems to be no question that when creosoting is well done it is effective."

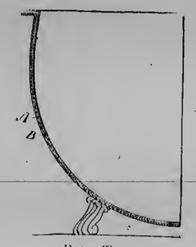
"It thus appears that there is no process of wood preserving the efficacy of which, when well done, is better established than creosoting."

"The conclusion drawn was that crude petroleum, by excluding moisture, would prove a preservative as long as it continually saturated the wood; but that if merely injected once for all, its volatile nature would result in its evaporating and leaving the timber unprotected."

RECENT CANADIAN PATENTS.

The following patents have recently been granted to Canadian inventors:—

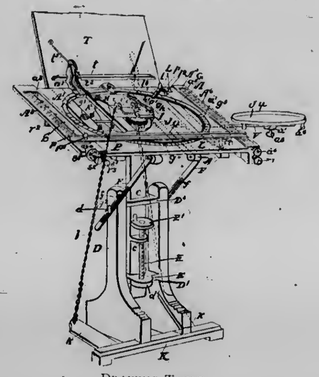
No. 48,804, for a bath tub, to George Booth, Toronto, Ontario, Canada, 1st May, 1895; 6 years.



Bath Tub.

A bath tub made in three sections, each section of which is composed of a sheet metal outer casing having an inner casing of copper, aluminum or other light, flexible material, and a lining of asbestos or other non-conducting material placed between the two casings substantially as and for the purpose specified.

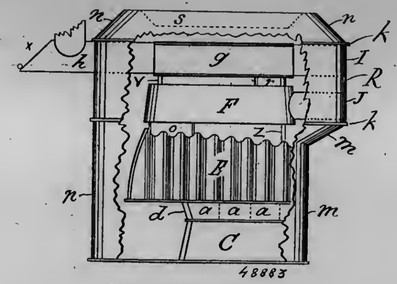
No. 48,825, for a drawing table, to Samuel John Laughlin and James Hough, both of Guelph, Ontario, Canada, and May, 1895; 6 years.



Drawing Table.

The combination with a circular drawing board G, the arc-shaped clasps O, pivoted at o, on the edge of the board and designed to fit between the bent retaining pin o', and the edge of the board over the turned down corner of the paper, a spindle H, journalled in the bars H, H, extending between the central cross-bars A', A', and having a square upper end extending into corresponding hole in the plate at the bottom of the board, a pulley I, on the spindle h, guiding pulleys i, i, on the spindle i', extending between the cross-bars, a chain secured to the pulley I, and extending over the guiding pulleys i, i, the lower end of the chain being connected to the forward end of the pedals k, and the cross-bar K, secured to the lower portion of the standard, and extending out each way, and having the pedals hinged to it, a catch g^4 in its edge and means for rotating the table of stops adjustably held at each side, and within the sweep of the catch, the stops being located at approximately ninety degrees apart so as to permit of a ninety degrees swing to the board, screw pins I' extending through blocks I^2, provided to adjust the stops to a nicety, a pivoted spring clamp secured at the rear of the table and having its free end extending over the board, a screw pin extending from the top of the table through the clamp, and a pressure knob screwed upon the screw pin above the clamp. The combination with the table A, provided with cross-bars and pivotally supported upon the spindle B, having bearings beneath the cross-bar upon the upper enlarged end of the vertical single standard C, the standards D, D having cross-bars D', through which the standard C extends, the bracket d' forming part of the cross-bar D', the bracket c forming part of the standard C, the screw spindle secured in the bracket D' and extending through the bracket c, and provided with a hand wheel, the slotted stays F, F' pivotally connected to the cross-bars A', and secured to the standards D, D by the thumb screw d, d, extending through the slots having the raised ends A^2 and A^3 and a circular opening a, and circular board G, rotatably supported within the opening and having its surface flush with the surface of its raised ends of the rule P, extending across the board and raised ends and connected at both ends to cords by depending blocks and means whereby the cords are given a uniformity of movement, so as to keep the rule when being moved parallel to the rear and front of the table, the cords being endless and extending around front and rear pulleys r and r', and wound around central pulleys r, which are secured at each end to the common spindle B, the scale A^6 held securely within the longitudinal recess a^5, in any definite position by the adjusting screw a^6, rotatable bar journalled in the recess a^3 and provided with longitudinal ratchet shaped notched strips and grooves longitudinally arranged, a catch tooth P depending from the rule and designed to engage with a notched strip of the bar when underneath the tooth, the scale marked collar s' on the supporting spindle s, the pointer S^3, knob s^4, toothed wheel s^5, and dog s^4. In a drawing table in combination a circular drawing board rotatably supported having a pointer on the edge of the board and a protractor arranged around half of the circumferential edge of the board, suitably divided and indexed from nought to ninety from the centre outwardly to each end, a spring clamp for holding the board in any desired position and a rule arranged to have a parallel movement to a straight line between the ends of the protractor.

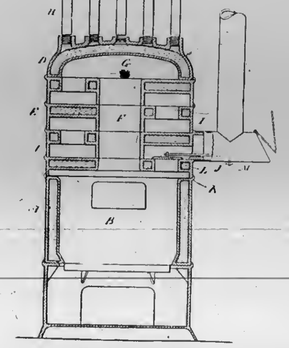
No. 48,883, for a domestic heating furnace, to John Albert Crossman and John Alfred Laws, both of Amherst, Nova Scotia, Canada, 8th May, 1895; 6 years.



Domestic Heating Furnace.

The combination in a domestic heating furnace of the ash-pit C, with the fire-pot d, and the body E, the combination of the body E with the radiator substantially as described.

No. 48,927, for a hot water boiler, to John Galt, Toronto, Ontario, Canada, 13th May, 1895; 6 years.



Hot-Water Boiler.

In a hot-water boiler, a series of water sections, each of the water sections provided with an upwardly curved lip extending into the outflow to prevent the upflow of the water, from the lower water sections, interfering with the outflow of the water from the said section, and provided with a downwardly curved lip extending into the inflow, to direct the water from the inflow into the respective water section. A downward passage from the secondary chamber to the outlet to the chimney, a central partition separating the upward passage from the downward passage, and the outflow pipes connected to the topmost water section substantially as specified.

There is a tendency toward stronger colors in paperhangings, says the New York Upholsterer. For several years the protest against the very delicate shades has been in progress, till now really dark colors can be used. This, of course, gives the decorator an opportunity to employ rich reds, vivid greens and glowing yellows. It gives him a better opportunity, also, to consider appropriateness in decoration. The rooms are different, and used for different purposes; hence, even in the cheap styles of decoration, he may select colors, not simple tints, to suit Radical colors, even, are coming into vogue.

The new Wesley College building at Winnipeg has been completed. It is the largest building devoted to educational purposes in the province, and cost $85,000.

The following is the Board of the Sydenham Glass Co., of Wallaceburg, Ont., for the ensuing year: Capt. J. W. Steinhoff, W. DeC. O'Grady, John Scott, George Mitchell, J. C. Shaw, J. H. Fraser, and D. A. Gordon.

The Winnipeg Commercial states that one of the features of the recent Industrial Exhibition, in that city, was a stove built specially for burning our native lignate coal. It is the invention of a resident of St. Paul, Minn.

P. A. Lariviere, W. E. Blumhart, Henry C. Bellew, and others are projectors of a scheme for the erection of a building to be known as the Auditorium, to be leased for use for opera, concerts, theatricals, exhibitions, etc., in Montreal.

Messrs. McCaskill, Dougall & Co. are erecting on St. Patrick and Manufacturers streets, Montreal, a large building for their varnish works and warehouses. It will be most complete and mordern in every respect, the latest English methods being adopted.

The striking plumbers of Buffalo are said to have played an ingenious trick on the master plumbers of that city. The fine in the United States for importing alien labor under contract amounts to $1,000 for each offence. Several Toronto plumbers obtained from the Buffalo bosses an agreement with their signatures attached engaging them to take the place of the strikers, and almost immediately on their arrival in Buffalo communicated with Inspector DeBirry, with the result that action was at once taken by the authorities against several plumbing firms.

TO ARCHITECTS

WANTED—Situation with view to PARTNERSHIP; eight years' experience in England; small salary.

Box 483, GALT, ONT.

TO ARCHITECTS, BUILDERS AND CONTRACTORS

We are prepared to furnish from our quarries in New Brunswick

BROWN AND OLIVE
FREE STONE
of the finest quality and of any dimension.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2⅞ × 3	2⅞	131,000	15,188	
C	2⅛ × 3	2⅞	130,000	14,751	
D	3 × 3	2⅞	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have a large quantity of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 9. SEPTEMBER, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 14th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

NOTWITHSTANDING the great advance in the price of iron, its use in building grows with rapid pace. It is estimated that the Carnegie Company has contracts on hand at present aggregating almost 1,000,000 tons of structural material, and no further contracts for delivery before three months can be accepted.

THE building permits granted in Toronto for August amounted to $95,215, as against $94,550 for the corresponding month of 1894. The total permits issued for the first seven months of the year were $1,094,065, and for the same period in 1894 they amounted to $774,895. This substantial increase is due largely to the re-building necessitated by the fires of last winter, but we believe there is a steady growth and that the city is slowly recovering from the disastrous effects of the boom.

BY the merest accident the cause of an acoustical defect, which had been attributed to faulty construction, was recently discovered in Trinity Church, Pittsburg, Penn. A magnificent organ had proved a disappointment, there being a lack of volume and a slightly muffled effect. This was ascribed to the position of the organ. It recently happened that the church was undergoing a thorough repairing and cleaning. The ingrain carpet and padding had been taken up. It was then noticed that the volume of sound from the organ was increased and that the muffled sound had entirely disappeared. The cause was thus, to the surprise of all, discovered to be in the carpet. It is probable a narrow strip of matting, or tiles, will be substituted for the carpet in the aisles. Perhaps the reason of defective acoustics in other buildings may be found to arise from a similar cause.

TWO native Canadians have just distinguished themselves and their country by their success in the competition for prizes offered for the best plans for two bridges over important waterways in the United States. Mr. Charles Macdonald, son of W. S. Macdonald, Esq., of Gananoque, of which town the former is a native, has won the prize for a design for a great railway bridge across the Hudson, between New York and Jersey City, to cost in the neighborhood of $25,000,000. The bridge will be shorter than the Victoria bridge at Montreal, and others in Europe and America, but it will surpass them in that it will have a single span of 3110 feet from one pier line to the other, which is nearly double the longest existing span in the world. It will be 125 feet wide, with six tracks, and is designed on the suspension plan, with steel towers 557 feet in height, and 12 cables supporting steel trusses, which rise 200 feet above the roadway. Mr. Andrew Onderdonk, the well-known contractor, is said to be associated with Mr. Macdonald in a company which will undertake the construction of the bridge, as soon as certain necessary preliminary arrangements are completed. Mr. Macdonald has already distinguished himself as a bridge engineer in Australia, and occupies the position of vice-president of the American Society of Civil Engineers. The other Canadian referred to is Prof. J. G. L. Waddell, a native of Port Hope, a noted bridge builder, and author of one of the best treatises

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

NOTWITHSTANDING the great advance in the price of iron, its use in building grows with rapid pace. It is estimated that the Carnegie Company has contracts on hand at present aggregating almost 1,000,000 tons of structural material, and no further contracts for delivery before three months can be accepted.

THE building permits granted in Toronto for August amounted to $95,215, as against $94,550 for the corresponding month of 1894. The total permits issued for the first seven months of the year were $1,094,065, and for the same period in 1894 they amounted to $774,895. This substantial increase is due largely to the re-building necessitated by the fires of last winter, but we believe there is a steady growth and that the city is slowly recovering from the disastrous effects of the boom.

BY the merest accident the cause of an acoustical defect, which had been attributed to faulty construction, was recently discovered in Trinity Church, Pittsburg, Penn. A magnificent organ had proved a disappointment, there being a lack of volume and a slightly muffled effect. This was ascribed to the position of the organ. It recently happened that the church was undergoing a thorough repairing and cleaning. The ingrain carpet and padding had been taken up. It was then noticed that the volume of sound from the organ was increased and that the muffled sound had entirely disappeared. The cause was thus, to the surprise of all, discovered to be in the carpet. It is probable a narrow strip of matting, or tiles, will be substituted for the carpet in the aisles. Perhaps the reason of defective acoustics in other buildings may be found to arise from a similar cause.

TWO native Canadians have just distinguished themselves and their country by their success in the competition for prizes offered for the best plans for two bridges over important waterways in the United States. Mr. Charles Macdonald, son of W. S. Macdonald, Esq., of Gananoque, of which town the former is a native, has won the prize for a design for a great railway bridge across the Hudson, between New York and Jersey City, to cost in the neighborhood of $25,000,000. The bridge will be shorter than the Victoria bridge at Montreal, and others in Europe and America, but it will surpass them in that it will have a single span of 3110 feet from one pier line to the other, which is nearly double the longest existing span in the world. It will be 125 feet wide, with six tracks, and is designed on the suspension plan, with steel towers 557 feet in height, and 12 cables supporting steel trusses, which rise 200 feet above the roadway. Mr. Andrew Onderdonk, the well-known contractor, is said to be associated with Mr. Macdonald in a company which will undertake the construction of the bridge, as soon as certain necessary preliminary arrangements are completed. Mr. Macdonald has already distinguished himself as a bridge engineer in Australia, and occupies the position of vice-president of the American Society of Civil Engineers. The other Canadian referred to is Prof. J. G. L. Waddell, a native of Port Hope, a noted bridge builder, and author of one of the best treatises

on the subject. Some years ago he was appointed Professor of Engineering in the University of Tokio, Japan, but subsequently returned to the United States, where he now practises his profession. The bridge for which he has prepared the successful plans is to cross the Missouri river.

WIRE nails have to a very large extent supplemented cut nails for building purposes. Many carpenters and builders, however, declare that wire nails for shingles are a failure. Their life is not more than six or seven years, or even less where large quantities of soft coal are burned, or near the sea. Along the Atlantic Coast copper or galvanized iron nails are taking the place of wire nails for shingles. The blame for leaky roofs may not he so much in the shingles as in the nails.

THERE is a city by-law in force in Toronto, limiting the area in certain classes of building, without a fire wall, to 4,000 square feet. There is some difference of opinion as to the wisdom of such a law. As a precaution against fires it is well to have it, while on the other hand, it restricts the size of large shops at the expense of appearance and convenience. As a matter of fact, the law is set at defiance in many cases. We could point to buildings now being built or re-constructed in which much larger areas than the law allows, without fire walls, are found. Buildings of larger area should at least be fire proof. While the law is there it should be enforced. If it is objectionable let it be repealed, but it is not right that it should be ignored. Is it not the duty of the building inspector to see to this?

AMONG the papers which were read at the recent meeting of the Medical Health Association for Ontario, was one by Mr. H. J. Bowman, Town Engineer, c. Berlin, Ont., on the "Possibility of Simple and Safe House Plumbing." Mr. Bowman's paper is in the nature of a review of the by-law attached to the Medical Health Act of 1884, which by-law is in force in all municipalities where it has not been superseded by one of their own. Having been passed so long ago, it is defective in some respects, in the light of fuller knowledge on sanitary questions and improved methods of plumbing, and Mr. Bowman points out a number of ways in which it should be altered, which will probably be done at the next session of the Ontario Legislature. The paper is a valuable one, and we shall endeavor to publish it in full in a future issue.

IMPROVEMENTS IN HOUSE DRAINAGE.

IN a paper read at a meeting of the Architectural League, Mr. Gerhard, C. E., Consulting Engineer for Sanitary Works, brought out a number of points relating to improved methods of house drainage in America. Some of these it will be of interest to note.

At the outset Mr. Gerhard refers to a noticeable improvement as to drainage plans. The practice has been to indicate the location of plumbing fixtures on the floor plans, but beyond this to give very little information. In consequence of the plumbing laws which have been enacted, it is now the custom to prepare a special drainage plan, on which the drainage and soil pipes are shown in detail, with size, and all other information necessary to enable contractors to make their estimates in an intelligent way. The workmen are assisted in that they can find by reference to the plans where the pipes are to be run, and architects and building superintendents are saved, because they do not require to spend so much time at the buildings and in answering questions. Well considered drainage plans are therefore of great assistance, especially in the case of large and important structures. The same holds true as to plumbing specifications. When too general in their character the result is that the estimates for the work run widely apart. The more detailed and accurate they are the closer will the figures be, and the more will the finished work conform to the expectations of the architect and his client. Extras will be avoided, at least the extras which the architect finds himself compelled to order on account of omissions in the original specifications. Mr. Gerhard condemns the use of the printed blank specifications of the building department, which, while convenient and labor-saving for the department, are not sufficiently detailed for anything but small buildings, or simple warehouses.

Turning to the question of material, Mr. Gerhard condemns the use of earthenware pipes, and commends the practise of using the same grade of pipe for the soil, drain and vent pipe systems of any building. In some cities the use of extra heavy pipe is compulsory, and Mr. Gerhard approves of it being so, and he further suggests that, in order to guard against sand-holes or imperfect seams, only pipes and fittings should be used which have been tested by hydrostatic pressure. He further advocates the more extensive use of screw-jointed wrought iron pipe for drainage, more especially in the case of high buildings. Architects and plumbers are coming to look with more favor on this class of material. Protection against rust at the joints is provided for by the use of coal tar or hot asphalt, or by the application of a process which renders the pipes rustless, or galvanized pipe may he used. The use of drawn lead and brass traps, instead of cast lead and lead with hand made seams, is commended.

Mr. Gerhard next refers to to the improvement as to the size of drains, commending small-sized pipes in preference to large ones, so long as they are of sufficient size to do their work. Two small drains are preferable to one large one, the reason being that the smaller sizes are better self-cleaners. An instance is given where a large building in New York, with 205 wash-basins, 24 sinks, 52 urinals, 62 water-closets, all the roof water, and other wastes, are carried off by two six-inch pipe sewers, with a fall of one-fourth inch to the foot. We presume many architects will not agree with Mr. Gerhard in this matter, but he has given the subject much study and his opinion should be worth something. The same principle he applies to soil and waste pipes, which are made smaller than formerly.

As to the method of laying drains, Mr. Gerhard condemns the practise of burying the pipes in the ground. Rather, he says, incase them in concrete, with man-holes at suitable intervals for examination or cleaning, but he favors the plan of suspending them from the ceiling or fastening them to the cellar wall.

Another point of improvement is the non-separation of bath, lavatory and sink wastes from water-closet and soil pipes. The double system is complicated and expensive, without corresponding advantage, and was the former practise in England, whence it was introduced to America. It was also the practise to have separate soil pipes from the baths and water-closets of each floor, making a complication of plumbing, with added expense. The tendency now is to simplify as much as possible, to group plumbing fixtures, and to concentrate the drainage in a single line of pipe, thus securing a well flushed line and economy in construction.

The common-sense system of open plumbing is highly commended by Mr. Gerhard. How the old plan of placing the pipes in a house under floors, behind plaster walls, and in other out-of-the-way places, where they were quite inaccessible in case of accident, ever came to be adopted seems incomprehensible.

Mr. Gerhard sees a great advance in the methods of house drainage adopted during the past ten years, and while we can recognize what has been done in the way of improvement, we must all admit that there is much room yet, before we reach a full conformity with the laws which nature has laid down for us in such matters.

PERSONAL.

Mr. W. A. Langton, architect, of Toronto, will leave for England in a few days. Mr. Langton has promised to give the ARCHITECT AND BUILDER the benefit of what comes under his notice in relation to architectural subjects.

Messrs. Arnoldi & Calderon, architects, of Ottawa, recently dissolved partnership. Mr. Arnoldi has just formed a new partnership with Mr. J. A. Ewart, under the style of Arnoldi & Ewart. Mr. A. M. Calderon is practising on his own account at new offices, 45 Elgin street.

Congratulations are in order for Mr. Sproat, of the firm of Darling, Sproat & Pearson, architects, of this city. An announcement in the marriage columns of the papers is the cause. On the 14th of August he led to the altar Miss Annie E. Harris, daughter of Mr. John Beverly Harris, of Tyndall avenue. The ARCHITECT AND BUILDER joins in best wishes.

Mr. Richard Dinnis, contractor for the carpenter work on the new court house, Toronto, met with an unfortunate accident recently which will lay him up for some time. He was driving along Front street with his little grandson and a servant, when a runaway horse dashed into his buggy and overturned it, throwing the occupants out. Mr. Dinnis suffered a dislocation of the shoulder and some severe cuts. The little boy was not seriously injured and the servant escaped unhurt. Mr. Dinnis is one of our oldest builders, having been in the business some forty years, and has numerous friends, who hope he will soon recover from the effects of the accident.

LIFTING A ROOF.

HOW A NEW STORY WAS ADDED TO A SCHOOL-HOUSE.—RAISING AND MOVING BUILDINGS.

SOME time ago the Board of Public School Trustees in Toronto found it necessary to provide more school accommodation in Parkdale. They had a good school-house, known as the Queen Victoria, which they wished to enlarge, but how best to do it was the question. It was 115ft. × 57ft. in size, two storeys high, with a brick addition 57 × 57 in rear. After consulting an architect it was decided to lift the roof, and build another storey, and the services of I. Wardell & Son, who make a specialty of such work, were called into requisition. They agreed for $800 to raise the roof, and replace it on the building after the new storey, 14 feet in height, had been added. The accompanying illustration, with a brief description, will show how it was done.

The roof of the addition was sawed off in line with the brick wall of the main building. The floors were shored from the basement up with stout timbers. Timbers were set in and needle beams put under the plates. A strong scaffold was built on the upper floor, on which the jack screws were to be worked. As the stone and brick pediments were to be lifted with the roof, needle beams, 12 × 14, were placed under them. Fifty-five jacks were employed to lift the main roof and 24 the addition. The jacks were the ordinary bottle jack, except those at the four corners, which were of the pattern known as anchor jacks. The roof was raised 6 feet, 13 men being employed to work the jacks. The joists for the new floor were then put in, and the jacks placed on them. The roof was raised 8 feet more and the brick wall for the new storey built up, when the roof was eased down till it rested upon the wall again.

PROCESS OF RAISING THE ROOF, QUEEN VICTORIA SCHOOL, PARKDALE.

As the roof, when resting on the jacks, would be liable to sag in the centre, provision had to be made for such a contingency. Two principles run from end to end of the building. They are about 115 feet long, and are 12×14 in size, built up of 2×14 joist. They were fastened together with a tie timber at each end to keep them in place, and 16 jacks, on a scaffold in the hallway in the centre, raised them simultaneously with the jacks around the outside.

The upper part of the tower with its roof was raised at the same time. It was supported on frame work, which rested on timbers suspended by chains from the plate. Two guy ropes served to steady it. To guard against the roof being dislodged by the wind while the work was in progress, purchase screws were attached and made fast to the joists of the first floor. The purchase screws were let out as the roof went up.

So well were operations carried out that the plaster of the ceiling was not cracked. It was considered advisable subsequently to remove it and substitute a metal ceiling.

The whole job was completed within 21 days from the commencement of operations. Not an accident or hitch of any kind occurred.

Wardell & Son, who carried out this job so successfully, make a specialty of raising and moving buildings, and have performed some clever feats in this line. Their most risky undertaking was at Kemp's Stamping Works near the Don. The factory stands on a side hill, and they underpinned it and held it up while the old foundations were removed and two new storeys built under. Work in the factory went on as usual all the time. The building is of brick, about 200 × 40 feet, and contains some very heavy machinery. So hazardous did the undertaking appear that some men declined to work on it, but it was successfully carried out without accident.

Last winter the same firm moved the hotel at Hanlan's Point 400 feet from where it formerly stood, and raised it with 100 jacks, so that a new storey could be built under it.

When the new water-front was made along the Esplanade they moved 13 buildings out to the new line, including the club house of the Argonauts. The latter was lifted on scows and floated to its new position. It was a difficult and risky operation, but was successfully accomplished, during the early morning, when the wash of passing steamers would not interfere with the work. They frequently remove brick and stone buildings from where they stood and turn them around so as to face in a different direction.

The firm consists of Mr. I. Wardell, an old wrecker, and his son. The senior member has been engaged in the business for some 40 years, the junior for 14 or 15 years, during the last 7 or 8 years of which he has been a partner.

LIME COMBINE.

THE Manitoba Grey Lime Burners' Association has been organized. The association comprises the lime-burners of Stonewall, Stony Mountain, St. Andrew's Parish, Gonor, East Selkirk and Tyndall. There is a local society at each point. Each member is bound not to sell lime unless he receives an order from the local secretary, who first receives it from the head secretary in Winnipeg, who divides the sales proportionately among the different localities. The price of lime has been raised to 18c. a bushel. All the burners in the Tyndall district, except one, have joined the association, and Mr. James Pruden is now burning a kiln to fill the first order sent him.

AN electric storm and cyclone visited Kingston on the 11th inst., wrecking the cotton mill badly and destroying much of the machinery. The water pipes were twisted and broken and the mill flooded. It will cost about $80,000, and take a month to repair the damage. The erecting shop of the K. & P. railroad was also wrecked.

THE ADVISABILITY OF THE REGISTRATION OF ARCHITECTS.

WITHIN a short time I have heard read two suggestive papers upon the architecture of the past in America—one being merely a resume of the records of the Boston Society of Architects from its formation in 1867; the other an account of the methods of the layman in New England and probably elsewhere of obtaining architectural service in the early forties and fifties. The records of the society showed a small body of earnest men dealing with comparatively small things, that is to say, with things small as compared with the buildings of to-day; there was a freshness, a *naivete*, about these records that caused a smile upon the faces of the men who had made them thirty years ago in their youth, and who were sitting about the table as they were read. There was no sign of recognition from the public in them, no expressed hope that the society formed should be recognized as representing the acknowledged leadership of the profession in Massachusetts, only a desire for mutual support, interest and criticism, and incidentally for architectural welfare. The other paper told of the constant custom of clients who went to England, bought copies of one-eighth-scale drawings of actual houses which had been built by English architects, and had, on their return, houses built from these plans by local builders.

All this is not so very long ago; in fact I can remember eighteen or twenty years ago that a building that cost $100,000 was considered quite exceptional in Boston at least, and until the great fire in Boston by far the largest amount of work done by the architects of that city was in suburban houses of small cost and in alterations of already existent buildings. The builder was a recognized individual as he still is; the architect was an occasional luxury. Under such circumstances it was not to be expected that he should be anything else. But with the growth of our cities, the concentration and increase of wealth, came requirements which the builder could not meet; and it was found that the architect was no longer a luxury, but a very earnest necessity.

Naturally as the demand for the services of the profession increased, coincidentally there appeared pretenders in its ranks; that is to say, there were plenty of men who neither had the adequate ability or sufficient application to thoroughly train themselves, who presumed to practice a profession which certainly required considerable study and attainments. Inasmuch as what services they had been able to give were quickly and cheaply prepared for, they were willing to perform them at a meagre price, but what under the circumstances was more than ample compensation.

Architecture having a distinctly commercial side was to be done by the lowest bidders. Of this class of practitioners little need be said, except that they are a curse to any profession, but in addition to these there have been and still are a number of very worthy men who insist in making their livelihood by practising a business under the name of art. This is legal enough,—no one can prevent it, no matter how much they may wish to do so,—and it occurs oftener from ignorance than from intention, but it nevertheless exists, and under what appear to be compensating conditions. As it happens, the man who makes an art into merely an artless business, either from the concentration of his thought upon one object, or by the very nature of his personality, is very apt to give the impression of being a so-called business man, and as such he appeals to business men and to their likes and dislikes, to their prejudices; and architecture so called thrives under the conjunction of the "practical architect" and the "practical" man. It should not be understood that the business side of architecture can be neglected, but that it should occupy, both in the architect's and the client's mind, its relatively just position, that is, that it is the necessary method of action that makes architecture itself actual and not imaginary.

The architect, unlike the sculptor and the painter, is in some factors of his profession necessary to the public; he is needed to carry out work which otherwise could not become existent; but on another side he is dependent upon the public for an opportunity to express himself. He occupies, therefore, the position of an executive who is limited in his action by the will of the sovereign people. In governments such a condition has proved satisfactory in proportion as both ruler and people are intelligent. In architecture it may be assumed, the result would be the same. The object to be attained then is to insure that the architect shall be intelligent, to hope that the public may be.

The burden of the proof of intelligence and ability lies with the architect. His chief credential is not pre-eminence as a business man, or even as a constructor, but as an artist. He will be judged by the next generation by that credential, and by no other. He owes to his client that he shall honestly and conscienciously fulfil his desires as far as possible as to expenditure; and that his building shall be abiding he owes both to his client and himself; but both these facts will be ignored in some fifty years. The judgment of the future passed upon an architect will always be upon his work as an artist and upon nothing else, and his influence will be proportionate to his skill as an artist alone. But in the meantime that chief credential is ignored, and the public choose their architects indiscriminately, and in many cases ask no credentials whatever. As a result "fools have rushed in," and architecture, though in better favor since the World's Fair, is glanced at askance and not recognized by many people as a profession equal to that of law and of medicine.

With whom lies the fault? Certainly not with the public or clients, for they assume, with true business understanding, that to be called an architect implies a knowledge of architecture, just as to be known as a cobbler implies a knowledge of shoes. We cannot blame them for lack of discrimination in their choice. How should they discriminate between men who are devotees of an art which requires long study for its attainment? Is it then a question of protecting ourselves against the pretenders in our ranks? This would seem to be an acknowledgment of weakness, of a callow state of affairs, which would defeat its own object. Surely the skilful man in any profession can take care of himself and afford to ignore inefficiency in others. If the public choose to be satisfied with worse than mediocrity, so much the worse for the public; why should we "fash" ourselves about it? But upon analysis the offence is greater than it first appears. Architecture is the most conspicuous of the arts, it is man's constant environment; and as he is very susceptible to the influence of surroundings, architecture has much to do with his education. If the public insist on employing men calling themselves architects, but who put up buildings bad in plan, construction, and appearance, then the trained architects, as citizens, should insist upon it that such work is detrimental to the public taste, that it mocks architecture itself, and that it should not be permitted.

The surest way of eradicating an evil is to deprive it of opportunity of action. If it were possible to diminish the numbers of the inefficients amongst architects, there would be a very perceptible change in our buildings and cities. Apparently the only way in which to do this is to restrict the right to practise architecture to those who have gained such a right by certain attainment. The making of plans and being paid for them cannot be restricted, but certainly the architects themselves have the right to say who shall be considered their peers. Give a dog a bad name, etc., can be paraphrased by give a man a good name and crown him. If it is once an established fact that all architects are obliged to show certain ability before they can practice architecture, the public will be thankful for that amount of certainty. The public are very prone to accept any profession at its own valuation, provided it maintains its own standard of excellence as announced. What should that standard be, and how should it be maintained?

The professions of law and medicine have long since determined their own action. A lawyer must be a member of the bar of his country, and the physician must have received his degree from a medical school; the fact of being a member of the bar or an M.D. guaranteeing the public a degree of training in each. Both imply lectures attended and examinations passed. A very small proportion of the public fail to assure themselves of the standing of their doctor or lawyer before they employ him. The restriction has elevated the profession in the eyes of the public. Would not the same result follow in architecture? In one country, Austro-Hungary, architects are only allowed to practice after having passed certain examinations; elsewhere the same universal chance for charlatans occurs. It will be urged that the charlatan will always exist, which may be very true, but he will be forced to be a clever charlatan, and that is a great gain. It will be said that the American Institute of Architects already give sufficient credentials to whoever desires them; but the American Institute, though more in evidence than formerly, is not known or recognized by the public to a corresponding extent as is the title of M.D., and leaves many able men out of its ranks, and occasionally excites antagonism. It is one thing to base one's pretentions upon known attainments, and another to base them upon membership with a body which must necessarily be fallible, and which is only lately donning the purple. Besides which, holding up the American Institute as a shibboleth does not lop off the dead wood of the profession, and the insistence upon attainment before practice does.

There is still another objection which will be made, that is, that the registration of architects is an autocratic and high-handed proceeding. This is based upon exactly the same error which considers that the best government is one where universal suffrage is allowed. A democracy of any kind averages things down before it begins to elevate. But while a democracy may be the best government, there is no need of a democracy in the profession of architecture. A profession, by its very name, implies the assumption of knowledge. My contention is that this assumption should be made a fact and that the only method of making it a fact is, by only allowing by law such men to be called architects as have shown reasons for being so called; in fact, to the legal registration of architects, and the institution of penalties for illegal use of the name. This will accomplish two ends: first, it will protect the public against charlatans; second, it will elevate the character of architects throughout the country. To my mind this is much more important than whether perspectives should be sent in competitions, or whether one style or another of architecture is the best to be found.

Our worst enemies are always to be found in our own ranks; the purpose should be to make them as harmless as possible. In the present condition of affairs the architect is called upon more and more frequently in matters of importance, but he has up to this time acted, been asked to act solely upon the basis of his personal reputation. How much more powerful would be such action if it could be the unanimous action of a body of men, that is, in matters of laying out of public improvements, of conceptions of large public undertakings! But the architect will always be crippled in the undertaking of reforms until the standing of his professinn is fixed and acknowledged. By the requirements for registration a standard will at least be attempted.

Necessarily that standard will at first be low. The first thing which has to be recognized is, that all persons calling themselves architects at present must be allowed to retain that title. A law of this kind cannot be made retroactive.

Second, the laws will be State laws, as are those of physicians; and, as was recently forced upon the notice of the physicians of Massachusetts, all the quacks will emigrate to the State having the weakest law. That was what occasioned the recent registration of physicians in Massachusetts.

Next, graduates of architectural schools must be admitted, as no discrimination can be made between schools, although it would be well to supplement school training with office experience. So far proposed action may be indicated definitely.

But what is to be done with the large body of draughtsmen who do not go to the schools, and with the considerable number of people who attempt architecture with neither school nor office training of any account? It is not wise to accept the recommendation of architects in whose offices the draughtsmen have been. Manifest personal qualifications are necessary. To determine these, examinations will be required. At once the two different tendencies of architectural students are to be acknowledged—the one towards art, the other towards construction and mathematics. Examinations should be made in both, and honors should be given in both. If no honors are received, especially in design, the applicant should be debarred. And just here comes the question of assumption of titles conferred as an invitation of attainment. The result of examinations in construction, mathematics, strength of materials, etc., can readily be determined; that of the examinations in artistic ability requires much more consideration.

It has already been said that an architect is primarily an artist, and will be ultimately judged as an artist, therefore he should be tested as an artist. It may be urged that his faculties may develop late. This is not usual with so-called artistic temperament, but in such a case he can try again. The examination for testing the capacity of design of an applicant cannot necessarily be more severe than school problems. It need not be as exacting in the matter of rendering, but it should test capabilities of handling plans, masses, and details, and it should also test creative skill.

By whom should such examinations be made? By a board of architects, not local, but from all over the country, appointed by the art commission of the city or State, if it possesses one, otherwise by the officers of the nearest Chapter of the Institute of American Architects. The art commission is suggested first, as it is a body representing the public more than do the Chapter of the Institute, and is constituted usually of men in recognized high positions.

Finally, in regard to the ethics of the profession. The Institute has not yet an established a code of ethics, except that it does not tolerate thieves. When it produces a code, after its adoption it should be voted upon by the architects of the country, and as much of it as is approved by their vote should be made mandatory and a law, and those violating this law should be debarred from the exercise of their profession.

If there are any strong objections to be made to the suggestions here made, I have yet to hear them. If carried out they will go far to produce the following results:—

They will clear the profession of much undesirable material.

They will remove all vagueness in the minds of the public as to its purpose and the ability of its members.

They will tend to eliminate bad architecture and stimulate good architecture.

Once this has been done, the members of the architectural profession will be consulted in regard to the designing of all important buildings, as the physicians are in regard to public health. Confidence in the ability of its members once given, and the architects of America, who will then be worthy of the name as a body, as well as individually, can do more to make this country famous for its art than can any other body of men. We are establishing scholarships, schools, and prizes of architecture; let us make evident the purpose for which these are established by giving the men so honored worthy competitors in their practice. Only to-day, in talking this over with a lawyer, I remarked: "You lawyers went through this long ago. What do you find is the result?" His answer was this: "It never keeps out anyone who ought to be in; the only trouble with the legal restriction is, that it still lets a number in who ought to be out."—C. Howard Walker in the Architectural Review.

PRESERVING WOOD BY LIME.

SOMEONE who has been experimenting on the preservation of wood by the use of lime, gives the result as follows:—"I have for many years been in the habit of preparing home-grown timber of the inferior sort of fir, Scotch spruce and silver, by steeping it in a tank, or a hole dug in clay or peat, which was fairly water-tight, in a saturated solution of lime. Its effect on the sap-wood is to so harden it and fill up its pores that it perfectly resists the attack of the little wood-boring beetle, and makes it, in fact, equally as durable as the made wood. I had a mill which was lofted with Scotch fir prepared in this way in 1850, and it is in perfect preservation. The timber is packed as closely as it will lie in the tank, water is let in, and unslaked lime is thrown on the top and well stirred about. There is no danger that the solution will not find its way to everything in the tank. I leave the wood in the solution for two or three months, by which time an inch board will be fully permeated by it. Joists and beams would, of course, take a longer time for saturation; but in practice we find that the protection afforded by two or three months' steeping is sufficient, if the scantlings are cut to the sizes at which they are to be used."

As the summer season is well nigh over, the meetings of the Toronto Master Plumbers' Association will be shortly resumed.

The death is announced of Mr. David Mitchell, only son of Rev. David Mitchell, formerly a Presbyterian minister in Toronto, lately of Jersey City. The young man was only 22 years of age, and was employed in an architect's office in New York. His death was the result of an accident.

ILLUSTRATIONS.

NEW GRAND OPERA HOTEL, TORONTO.—HENRY SIMPSON, ARCHITECT.

STAIRCASE HALL IN A. E. KEMP'S HOUSE, WELLESLEY CRESCENT, TORONTO.—E. BURKE, ARCHITECT.

PROPOSED ADDITION TO THE LAKESIDE HOME, TORONTO.—CURRY, BAKER & CO., ARCHITECTS.

The building which we illustrate is designed to occupy a site separate from the Home proper, and is intended for the use of the nurses.

CONVENT OF THE SISTERS OF ST. CROIX, MONTREAL.—J. B. RESTHER & SON, ARCHITECTS.

THE building now in course of erection for the Reverend Sisters of the Congregation of "Ste Croix et des Sept Douleurs," is situated on the north side of Mount Royal Avenue, extending from Rivard street to Berri, a frontage of 150 feet. In plan, it is that generally adopted in buildings for educational purposes, with corridors on each storey, running the entire length of building, and large commodious staircases and elevators.

The corridors lead to large rooms used as class rooms, parlors, studios, etc. These are all well lighted and ventilated. The heating apparatus is the hot water system; the boilers being centrally situated renders the distribution easy and effective. All the most improved plumbing and other appliances have been devised to insure comfort to the inmates.

The main building is 150 ft. in length, 62 ft. wide and four storeys high, with an eastern wing 27 ft. wide, 42 ft. long, two storeys high; a western wing 33 ft. wide, 52 ft. long, three storeys high. All substantially built of Montreal lime stone; the front and sides are of rock faced ashlar, with cut stone bands, chiselled sills, lintels, quoins, trimmings and moulded course.

The beams and columns supporting the interior structure are of steel throughout; the interior partitions and furring to outer walls are of terra cotta lumber. The first floor is devoted to the infants' course refectories, kitchen, laundry, &c., while the second floor is restricted to the administration, the third floor is mainly composed of class rooms, the chapel in the western wing being 75 ft. long, 28 ft. wide, 17 ft. high in the clear; the fourth floor to be occupied as a general dormitory. The building to have improved fire escapes and to accommodate two hundred pupils, chiefly boarders.

ANNUAL CONVENTION OF THE PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE annual convention of the Province of Quebec Association of Architects is announced to take place on the 2nd of October, the place of meeting being the city of Quebec. At the time of going to press the program is as yet incomplete, and we are therefore unable to give full particulars, but it is anticipated that papers will be presented by several members of the Association. Some amendments to the charter, proposed by the Quebec members, will be considered, but it is said that should the said amendments be adopted, the position of the Association will not be altered. The members should endeavor to make the convention a success.

SUDDEN DEATH OF A WELL-KNOWN ARCHITECT.

MR. G. F. STALKER, a well-known architect of Ottawa, died suddenly the other day. He left his house in the evening apparently in his usual health, and soon after was found lying insensible on the steps of Rideau Club. A cab was called, but when he reached home he was dead. An inquest was held and the cause of death declared to be apoplexy.

Deceased was a native of Scotland, and was 54 years of age. He came to Canada in 1883, and except for one year, spent in the public works department, he has been in business for himself in Ottawa ever since. He leaves a wife and nine children, the eldest 20 years of age. Mr. Stalker was well known as an architect. He drew the plans for the cottage hospitals on Porter's Island, and his plans for the new central railway station at Ottawa had just been accepted.

PUBLICATIONS.

Fiction and travel are the strong points of the September Cosmopolitan, and it may be said that no more beautifully illustrated number of the Cosmopolitan has ever been given to the public.

STUDENTS' DEPARTMENT.

CONCRETE FLOORS FOR STABLES.

A SUBSCRIBER inquires how to lay a concrete floor for a stable.

The floor should consist of three layers, first, about three inches of broken stone and brick, in pieces that will pass through a three inch ring, second, 2½ inches of gravel, sand and cement, mixed in proportions of 4 of gravel and sand and one of cement, topped off with a ½ inch floated coat of clean sharp sand and cement, mixed in proportions of two of sand to one of cement (best Portland cement to be used). The floor is to be so laid to have proper fall to drain off all water, and provision is to be made for this. The usual method is to give it a slope to the rear, where there is a gutter to carry off the liquid matter. The surface of the top coat should be scored.

As concrete makes a hard and unyielding floor for a horse to stand on, planks may be laid down over it, which can be easily removed for cleansing and airing. Instead of the plank, sawdust may be employed. It makes good bedding, is soft under the horses' feet, and is cheap. What is soiled can be removed every day and replaced by fresh.

Vitrified brick is considered by some as making a better stable floor than concrete.

USEFUL HINTS.

A new kind of veneering material is reported from Germany. This is composed principally of infusorial earth mixed with various binding and coloring ingredients, and spread in layers over a wooden core; on the mass becoming dry, it is cut into sheets or blocks, which resemble, in effect that of figured wood.

The American Druggist recommends the following formula for waxing hardwood floors: Yellow wax, 25 ounces; yellow ceresin, 25 ounces; burned sienna, 5 ounces; boiled linseed oil, 1 ounce; spirits of turpentine, 1 gill, or about 30 ounces. Mix the wax and ceresin at a gentle heat, then add the sienna, previously well trituated with the boiled linseed oil, and mix well. When the mixture begins to cool add the turpentine, or so much of it as is required to make a mass of the consistency of an ointment.

The free circulation of water in steam or hot water heating boilers is one of more importance, says the Master Steam Fitter, than is generally considered, because where the circulation is obstructed a certain amount of power is required to overcome friction to produce the circulation necessary for the free development of steam. Restricted or otherwise obstructed circulation always calls for more fuel to produce a given heating effect. This is practically shown when comparing the action of two boilers of the same pattern but of different size, especially those used for heating purposes.

A safe, constructed of cement with steel wire netting embedded in it, was recently tested at the Reichsbank, the official bank of the German Government, in order to decide whether it is practicable to build safety vaults of this material, which will be proof against fire. The test, which was most severe, consisted in placing the safe upon a pile of logs soaked with kerosene, which were then set on fire, the safe being exposed for half an hour to a heat of 1,800 degrees F. Two hours later the safe was opened, and the contents, consisting of silk, paper, blank drafts and a maximum thermometer, were found to be entirely uninjured. The maximum thermometer showed that the temperature inside the safe at no time exceeded 85 degrees

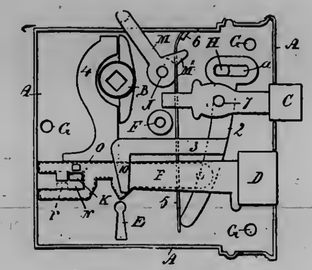
Buildings divided into offices, consultation rooms, dormitories, or "light housekeeping" apartments for the use of many occupants, require, says a contemporary, not only thoroughly deadened floors, but extra care in perfecting the partition walls. Two coat, or better, three-coat work in plastering should be specified, continued down close to the floors, to prevent the passage of air or sound. The first coat is usually neither very even nor smooth, partaking of the inequalities of the lathing, and purposely left rough as a foundation for the next or brown coat. Care should be observed in putting on this second coat, to make the walls straight and true by filling up and leveling out malformations visible in the first coat. The third, or last coat, the white finish, is too thin to hide any defects of this kind. On the contrary, it is understood that the finer the finish of the last coat, the more sensibly will the inequalities of the surface appear.

RUST OF STEEL AND IRON.—Iron and steel with a perfectly bright surface do not rust in absolutely pure water or air; carbonic acid, or similar agent, must be present. Moisture, carbonic acid and oxygen being present, oxidation is not produced so long as vapor of water is not condensed upon the surface of the metal. In rusting, carbonate of iron is formed, which is dissolved in the water charged with carbonic acid and transformed into bicarbonate. In the presence of air this is decomposed and gives magnetic oxide, then a hydrated oxide of iron. Polished iron and steel resist oxidation for a long time, but once started the rust forms rapidly and soon spreads over the entire surface. This is because the oxide of iron formed is electro-positive relatively to the iron, and is very hygroscopic, facilitating the absorption of moisture from the air. Steel and cast iron rust more easily than the purer metal; the more pure the iron is, the more it is subject to oxidation.

RECENT CANADIAN PATENTS.

The following patents have been granted at Ottawa to Canadian inventors:—

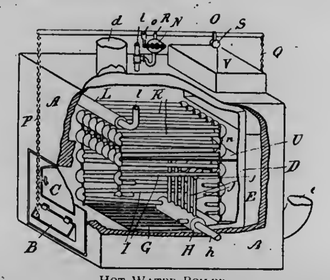
No. 49,420, for a combined Latch and Lock, to Alexander Watson, Kinmount, Ontario, Canada, 8th July, 1895; 6 years.



COMBINED LATCH AND LOCK.

Claim.—The combination, with the lock case, safety catch M, sliding latch C, locking bolt D, and tappet B through which the knob spindle passes, of the lever 2, having arms 3, 4, and a spring 5, engaging said lever near the free end, said lever pivoted slidingly to the lock case through an elongated eye a, and the arm 4 engaging the tappet and having frictional contact with the tail of the locking bolt, and the latch loosely connected to said lever, as and for the purpose set forth.

No. 49,547, for a Hot Water Boiler, to John D. McEachren, Galt, Ontario, Canada, 23rd July, 1895; 6 years.

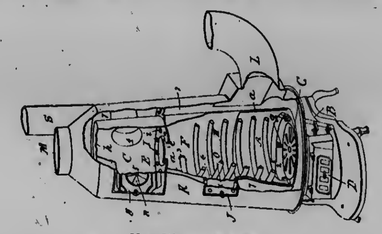


HOT WATER BOILER.

Claim.—1st. A hot water or steam boiler having an inner and outer casing, the said inner casing being of metal or other suitable material as ventilation may be required and the outer casing of brick work, a space between the said casings, an air inlet and an air outlet communicating with said space, a series of tubes forming the boiler, the said tubes forming the sides, end and top of the fire box, substantially as set forth. 2nd. In a brick set boiler, the combination with the brick work A, of the metal or other suitable material, lining D surrounding the boiler and furnace, substantially as set forth. 3rd. In a hot water or steam boiler, the combination with the fire box of the tubes or coils I, forming the sides of the said fire box, substantially as set forth. 4th. In a tubular boiler, the combination with the tubes forming said boiler of the counter bored fitings M, substantially as set forth. 5th. In a tubular boiler, the combination with the tubes forming the said boiler of the counters bored fitting M, having a hollow depending supporting lug n, whereby the said tubes are splayed and supported, substantially as set forth. 6th. The fitting M, being counter bored, and also threaded for the reception of tubes or pipes, as and for the purpose set forth.

No. 49,519, for a Hot Water Boiler, to John D. McEachren, Galt, Ontario, Canada, 18th July, 1895; 6 years.

Claim.—1st. In a portable hot water boiler, the combination with a boiler consisting of a fire pot, fire chamber and combustion chamber of a conical shape, a hot water coil contained in the said fire pot and fire chamber, of an outer casting jacket forming a ventilating space around the said fire pot, fire chamber and combustion chamber and an air inlet and air outlet connected with the space so formed, substantially as set forth. 2nd. In a portable hot water boiler, the combination, with the hot water coil H, of the supports g, in which the said coil rests substantially as set forth. 3rd. In a portable hot water boiler enclosed in an inner and outer casing, having a heating coil spirally arranged and fire pot enclosed in the said inner casing, the combination with the said inner and outer casing having openings situated above the said fire pot, and connected together, of the door J, and sliding-door O, substantially as set forth. 4th. In a portable hot water boiler, the combination with the fire pot, grate and fire chamber, having a spirally arranged conical shaped coil located therein, of the combustion chamber located above the said fire chamber, a diaphragm having a central opening and deflecting plate, separating the said fire chamber from the said combustion chamber. 5th. In a portable hot water boiler, the combination with the fire chamber and combustion chamber, of a diaphragm having a



HOT WATER BOILER.

central aperture and a series of perforations around the said aperture, and a movable deflecting plate over the said central aperture, substantially as set forth.

Patents have also been issued to R. H. Stilwell, of Detroit, Mich., for a form of matched board; to W. M. S. Garrison, of Elizabeth, N.J., for a portable elevator; to C. G. Davies, of Denton Harbour, Mich., for a brick machine; to Sam. Hughes, of Lindsay, Ont., for a window sash and sash frame, and to C. J. Cooze, Charterton, Wellington, New Zealand, for a window sash.

THE OLD CRYSTAL PALACE.—A REMINISCENCE.

MR. Edwards, Secretary of the Department of Public Works for Ontario, has been hunting up the history of the crystal palace, which stood so many years on the old exhibition ground, immediately south of the lunatic asylum in Toronto, and which was afterwards taken down and removed to the present exhibition park, where it still does duty as the upper part of the Main Building at the Industrial. It is quite interesting.

The corner stone was laid on the 15th of July, 1858, by Hon. E. M. Vankoughnet, Minister of Agriculture, the officers of the Agricultural and Arts Association being as follows:—

D. B. Stevenson, president; Wm. Ferguson and John Wade, vice-presidents; Richard L. Denison, treasurer; Prof. Ed. Buckland and Wm. Edwards, joint secretaries; Prof. Henry Croft, chemist, and James Fleming, seedsman. These gentlemen and the following formed the Toronto Local Committee: W. H. Boulton, Mayor; F. W. Jarvis, sheriff; W. B. Jarvis, Rev. Dr. McCaul, Dr. Daniel Wilson, Ald. Reid, Ald. Brunel, Ald. Bonmer, Ald. Ritchie, Ald. Carr, J. E. Pell, Samuel Walton, J. D. Humphries, Joseph Hartman, M.P.P., warden; Geo. T. Denison, Alexander Shaw, Prof. Buckland and all the members of the Board of Agriculture.

The only surviving members are:—Wm. Edwards, ex-Ald. Reid, ex-Ald. Ritchie, John E. Pell and Samuel Walton.

The architects were Fleming & Schreiber, now Dr. Sandford Fleming and Collingwood Schreiber, Deputy Minister and Chief Engineer of the Department of Railways and Canals at Ottawa. The amount paid the contractors, Smith & Burke, for the completed building was $20,804.92. The building was principally iron and glass, and was 256 feet in length, 144 feet in breadth and 56 feet in height. It contained 2,000 square feet of glass in the roof and 5,000 feet in the walls, its gross weight being twelve tons. There were only three kinds of castings in the building—the ground columns and the girders, each 16 feet long, and a shorter column from the gallery floors to carry the roof. The iron frame was then in 16 feet squares and was held in form by iron screw bolts and clamps, and the entire building—columns, girders and circular roof ribs—were unbolted and taken apart with the breakage of only three pieces of the castings.

AN ARCH COLLAPSES.

A FEW days ago the big brick arch forming the portal of the Toronto, Hamilton and Buffalo tunnel under Hunter street, Hamilton, fell with a crash, fortunately without injuring anyone. The chamber, or support, of the eastern half of the arch had been removed. The sides were not strong enough to stand the strain, and bulged out, and the unsupported part of the arch fell. The accident was also partly due to the sand in the cement not being strong enough. About 40,000 bricks had been used in the arch, all of which will have to be removed. The loss will fall upon Mr. Onderdonk, the contractor for the tunnel.

CONCRETE FLOORS.

THE subject of concrete opens a wide field for investigation and discussion, but in a series of articles on the subject, in the Contract Journal, Mr. Geo. H. Blagrove confines himself to the consideration of its uses in the construction of floors. Slabs of concrete, he says, supported upon girders or rolled joists of iron or steel, form a species of floor which is coming more and more into general use, and it is our present purpose to indicate as accurately as possible the capabilities of the material so employed and the best means of turning those capabilities to advantage.

It may be premised that the concrete referred to here is composed with Portland cement, not with lime. As regards the quality of the cement for this purpose, much that is instructive may be gathered from the writings of scientific experts. Practical men usually adhere to a few plain rules which occasionally receive modification when some newly-discovered fact meets with general acceptance. Thus, for instance, the specification for a recent contract required that the cement used in making concrete should be of such a degree of fineness that a sieve of 2,500 meshes per square inch should not reject more than 12 per cent. of the powder when gently shaken. Scientific tests have shown that great additional strength is obtainable with higher degrees of fineness, but anything beyond the ordinary degree seems rarely to be insisted on in practice. We shall assume that the cement with which we deal is of the quality stated, that it weighs at least 112 lbs. per striked bushel, or nearly 90 lbs. per cubic foot, and that a briquette of neat cement will have an ultimate tensile resistance of 400 lbs. per square inch after six days' immersion in water. To prevent any possibility of its being used hot, and so being liable to crack after setting, it may be required to be kept for a month or six weeks after being mixed, and may be spread out upon a floor and turned over daily during the last two or three weeks. The question of chemical analysis is rarely approached in ordinary practice. It is generally admitted, however, by experts, that the cement should contain about 60 per cent. of lime, about 24 per cent. of silica, and about 11 per cent. of alumina, the remaining 5 per cent. being made up of magnesia and alkalies.

Supposing the ingredients to be thoroughly mixed, we should obtain a concrete upon which some reliance could be placed for its resistance to transverse stress. But this thorough mixing embraces the requirement often insisted upon that every particle of sand and coarse aggregate shall be completely coated with cement. If there should be an absense of cohesion in any part of the mass, all calculations of strength may be at fault.

The question of the nature and proper proportions of the ingredients for making Portland cement concrete is indeed a wide one. As bearing upon the construction of floors, valuable information is afforded by the results of Mr. Darnton Hutton's experiments described in course of the discussion of Mr. John Grant's paper on "Portland Cement" at the Institution of Civil Engineers.* Mr. Hutton experimented with bars of concrete 4 ft. long and 1 ft. square, supported upon a 3 ft. span and broken by means of a load hung from the centre. The general proportions of cement to other materials was 1 to 9, though sometimes higher. With 1 cement, 5 shingle, and 4 sand, the central breaking weight was 2,656 lbs. With 1 cement, 5 shingle, and 3 sand, or a proportion of 1 to 8, the breaking weight was increased to 3,023 lbs., an increase of about 14 per cent. But on reverting to the proportion of 1 to 9, with 9 parts of shingle only to 1 of cement, the breaking weight was increased to 9,590 lbs. The inevitable conclusion is that for transverse resistance sand is a source of weakness, and should be omitted. But everything would appear to depend upon the careful mixing of the ingredients. Without sand, and with an unequal admixture of cement and water, the cement might have a tendency to honeycomb in the interstices between the particles of aggregate, and this would be less likely to occur if sand were used. As a general rule, therefore, with ordinary workmanship, it would seem safer not to dispense with sand. As might have been expected, experiments generally show that the greater the proportion of cement the greater is the transverse strength, and of course the tensile strength of the cement is an important factor. It is remarkable, however, that in some of the experiments of Mr. Alexander Fairlie Bruce, to which further reference will be made,† a higher degree of strength in the cement was accompanied by a lower transverse resistance in the concrete when the proportions of sand and coarse aggregate were unaltered. This is only one of many instances that could be cited of the capricious behavior of concrete under transverse stress.

Among several kinds of aggregate employed by Mr. Bruce, he found gravel to be the least absorbent, and therefore the most economical. But as regards transverse strength, the general results of his experiments tell in favor of hard sandstone. It is probable that the cement obtains a better hold upon an absorbent than a non-absorbent substance.

It is difficult to lay down any rule which would govern the proportion of thickness to span in concrete floors. But apart from the theory of transverse resistance, we may suggest that the proportion of the thickness to the size of the coarse aggregate ought to have an important influence upon the strength, especially if it be assumed that fracture is most like to take place in the joints between the cement and the aggregate. Other things being equal, the thicker slabs ought to show a higher degree of transverse resistance, as being relatively more homogeneous than thin slabs in which the pieces of aggregate are few in depth and have but little chance of breaking joint.

Among some of the earliest recorded experiments upon the transverse strength of concrete floors is one mentioned by Mr. Potter in his work on "Concrete: Its Use in Building." A slab of concrete, made with two bushels of Portland cement and nine bushels of crushed slag, was tested one month after manufacture. The slab measured 6 ft. by 4 ft. 9 in. and 5 inches thick, and its two longer sides were supported upon 2 in. solid bearings, the other two sides being left free. It was loaded with 550 bricks, and also subjected to considerable impingement, but did not give way, the weight supported being equivalent to about 140 lb. per square foot. In this case the thickness of the slab was less than one-tenth of the clear span, a proportion that would hardly be thought safe in practice An ordinary proportion for small spans is 11-sixths, as in the case of a 4 in. thickness for a 2 ft. span, or a 6 in. thickness for a 3 ft. span. With larger spans and greater thicknesses, the proportionate thickness might be reduced according to the load to be supported. If the laws of transverse resistance are to be applied to concrete slabs, it will follow that the strength will vary inversely as the span and directly as the square of the thickness. But when there is a certain stated load per square foot to be carried, the total amount of load will vary as the span, and the strength must be made to vary in the same proportion. Hence the square of the thickness should vary as the square of the span, or, in other words there should be a constant ratio between thicknesses and span for any stated load per foot.

THE NEW LEGISLATIVE BUILDINGS, VICTORIA, B. C.

VICTORIA, B.C., Aug, 24th, 1895.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Your reference in this month's CANADIAN ARCHITECT AND BUILDER in respect to the foreign oak used in the above building, rather exaggerates the case. As a matter of fact the whole of the numerous offices and rooms of the new Parliament Buildings are panelled and finished in British Columbia lumber —cedar, maple, alder, spruce and fir—except only two small rooms, which are partially panelled in oak; and also, when the rooms are finished in cedar, some of the doors which will be subjected to rough usage are of oak—the oak harmonizing with the cedar better than any wood I know of, the cedar itself being too soft for hard wear and tear. You will thus see that the amount of foreign wood used is comparatively trifling.

It has been the earnest desire of everyone connected with our new Parliament Buildings, to utilize as far as possible local and and native materials, and we have done so to an extent rarely equalled, I should think, in any building of similar importance.

Yours faithfully,

F. M. RATTENBURY, Architect.

THE Don Valley Pressed Brick Works have just turned out their first kiln of paving bricks, which are considered by experts to be equal, if not superior, to any made on the continent.

MANUFACTURES AND MATERIALS

QUALITIES OF BUILDING-STONE.*

By Maurice Thompson.

THE qualities necessary to the best possible building-stone are, workability, durability and beauty. It must also be cheap.

Workability includes in its meaning, accessibility, a ready yielding to quarrying operations, the absence of refractory qualities under the hammer and chisel, and a texture and grain that will hold decorative finish.

Stone that cannot be quarried readily has the disadvantage of great cost to begin with. If the "raw material" is expensive, the finished product must be costly. On the other hand, if nature has so deposited her stores that the stone is easily taken from the quarry, still, if the material is refractory in the final cutting and finishing; no matter what may be its other qualities, it cannot be a very cheap material for the builder, as it will demand an over amount of expense and delay in preparation. Still less will it be desirable if it obstinately refuses to hold finish or decoration. Stone that comes from the quarry soft, and yet somewhat tough, but hardening after a time, has the finest quality of workability. This renders it easy to quarry, very responsive to the tools of the cutter, and capable of taking easily, and holding permanently, the finish and decorative designs of the architect's specifications. It must be kept in mind, however, in axamining stone, that it comes from the quarry wet, and for that reason easily workable, it may again take up water after drying, which would be most objectionable; but if, in the process of drying in the first place, it passes through a chemical change which will render it ever afterwards impervious to water, the quality is just what could be wished for in this regard. Usually an examination of the outcropping surfaces of the stone in place will give a safe knowledge of its value as regards workability. Next, after the character of the stone, regard must be had touching the condition of its deposit. Too much overlying matter, whether stone or earth, will usually make the quarry work very heavy and expensive. This overlying matter, technically called "stripping," is, as a rule, quite worthless, and must be entirely removed before the stone can be worked with steam channelers or other quarrying appliances, hence the necessity of a careful examination to determine its nature and extent in each case before opening a quarry.

Durability, as applied to building-stone, includes every quality tending to make the material lasting and unchangeable after it is laid in a structure. These qualities are many, and often seemingly conflicting in their nature. Hardness, elasticity, tensile strength, power to resist the greatest crushing force, imperviousness to water, and invulnerability to the attacks of air and its corrosive and disintegrative burdens, are some of the qualities, but not all. Evenness and homogeneity of composition, unity of substance, so to speak, and the power to resist extremes of heat and cold, are quite as necessary. It will be seen at once that chemical analysis must be relied on to insure the best knowledge of some of these requirements. Some otherwise good and durable limestones will become corroded and discolored, and have their integrity destroyed by the effect of sulphurous smoke from the burning of impure coals; others will be injuriously affected by the action of rain-water, and still others by the oxidizing power of the air. Some sandstones bear too much iron in their composition; others lack sufficient cohesion of the particles, while others again are clayey, or unequal in grain or texture. Every test of practical science should be given to stone before it is used in any building intended to be a permanent structure. As a rule, if the outcropping ledges are found to be infiltrated with water, which makes the outer surface constantly damp, the stone will not be good, for this would indicate that it would take up too much moisture in the wall. Still, it is often the case that an apparently over-hydrous stone will dry out permanently after it is quarried and cut. Many of the sandstones, notably the better qualities of conglomerate, are of this character, and so soft when first taken out that they may be cut to any rough shape with a common axe or hatchet, but hardening after a few days' exposure so that water will not affect them.

The elasticity of stone may be tested by sawing it into long, slender strips, say two inches square and three feet long, when, if it be quite perceptibly flexible, its elasticity is good. If such a bar be suspended so as to hang free by a string, and is struck a light blow with a hammer, its evenness and solidity of fibre will be attested by a clear, sweet metallic note, not unlike that of a fine bell, or that of a well tempered steel bar. As a rule, the best stone will break with a direct line of fracture; but it may be conchoidal, or otherwise indirect, and still be unobjectionable. Parallel lines of cleavage, or of stratification, are always favorable indications where other features are promising.

Resistance to crushing weight may be pretty safely inferred from solidity of texture and evenness of grain; but it is always necessary, before a final acceptance, to submit the material to the severest tests of an apparatus designed for that purpose. This will be described in the proper place.

In examining sandstone, with a view to building purposes, the outcropping, if there be any, should be carefully scanned with a view to discovering what effect long exposure to the atmosphere and the rigors of winter may have had upon it. If the stone has "weathered" badly, this will be shown by one or another sign of disintegration or demolition, and a talus of fragments and sand will be found formed at or near the base of the outcropping cliff. Often the substance of the rock will give unmistakable evidence of inequalities of structural composition, such as horizontal cavities caused by the weathering out of seams or streaks, that, on account of bearing too much iron, have oxidized and crumbled away. Such stone, if used in a building, would prove worthless, and, therefore dangerous. It is often the case, as I have observed during a long experience, in civil engineering, that public bridges erected by counties are rendered unsafe by having their piers and abutments constructed of this kind of stone, and that, too, in places where most excellent material lay near at hand, and which a little knowledge of the nature of the stone would have pointed out to the superintendent. Too frequently it happens that appearances of the most untrustworthy kind are relied upon where an ignorant person is set to do work which ought to be in charge of a skilled and well-informed engineer.

In judging of the probable durability of limestone, before subjecting it to any test of science, the same observations should be made as in the case of sandstone, with a view to ascertaining its weathering qualities. Any unequal discoloration of the face of the exposed ledge should be scrutinized carefully. Usually these are caused by the presence of iron in the composition of the rock. But limestones are much more injuriously affected by hidden faults of composition than are sandstones, and for this reason they demand a much more careful examination before any extensive quarries are opened. It is often the case that iron in limestone will do no more than discolor the outer surface on exposure to the action of air and rain-water; but even this is a serious defect when the stone is to be used in any structure wherein beauty is a chief object. For the rough masonry of ordinary bridges, and for the hidden foundations of buildings, a cheap and durable stone is what is most wanted, and in these discolorations is not a fatal fault.

Beauty, when the term is applied to any building material, includes all the good qualities already enumerated, with the added value of a pleasing color, or combination of colors, and a general effectiveness of appearance when the structure in which it is used has been completed. The variegated granites undoubtedly are the most beautiful of all building materials. Next to granite, the red and brown sandstones are most pleasing to the eye, but the white, gray and blue limestones are very effective, and they have the advantage over granite in that they work much more easily in ornamentation, while they take figures in relief with far more clearness of action than do the sandstones as a rule. Architects have long since discovered the pleasing effects to be produced by using different kinds of stones in the same building, placing each where its particular qualities will best serve the general motive of the design.

As a rule, all else being equal, the stone which holds its native color best will be most beautiful in a building; and of the stones which change color, that will be most desirable which changes least and evenly. Some of the gray sandstones, however, change color unevenly, and give a striking and ofttimes picturesque cloudiness to the surface, which adds to its effectiveness of color in a wall. The nearly white limestones that take on by exposure a dark cream-brown hue, if they do not contain too much magnesia, hold that tint very well, and are quite beautiful. As a rule, the presence of many large animal remains in a stone is objectionable on account of the tendency of such a composition to crumble; but where the fossiliferous rock is durable, it will usually be found very beautiful when cut, the organic remains bossing it over with variegation, that greatly heighten its appearance. Stone which contains large fossils is not, however, the best for receiving raised ornamentations, such as figures in relief, no matter how durable and beautiful it may be, for the animal form will interfere with nicety of cutting and polish, as well as with the regularity of the figures. Fossils will usually be found harder than the matrix in which they are set; but this is not always the case, for quite often the form is that of a hollow cast or impress, filled in with material which crumbles easily. As a rule, fossils, though very hard, are but loosely set in sandstone, and often they are very large and rough forms of plants, extremely silicious and refractory. Blocks containing these are to be avoided as probably worthless for building purposes, however valuable and interesting they may be from a scientific point of view.

Many very beautiful stones that are not durable when exposed to the weather, are very valuable for the inside finishing of buildings, where they will last for ages, holding the finest tints of their coloring without perceptible change.

From what has been said above, it will be seen that every owner of

* From the Seventeenth Indiana Geological Report.

stone beds, should, before going to the expense of opening quarries, have his rock beds examined by an expert, whose report should show all the defects as well as all the good qualities of the material. Usually this can be done without any great outlay of labor or money, for the experienced geologist or engineer can quickly discover from the stone and its surroundings the nature of the deposit, and very simple chemical and mechanical tests will settle the question of strength and durability. There are beds of magnificent building-stone lying undeveloped in many places, simply for the reason that the owners are not aware of the treasure that they possess. In other places quarries are being industriously worked and the stone used in the erection of costly buildings, where, in fact, the material is wholly unfit for use on account of its lack of durability. I have examined many extensive structures whose stone was fast crumbling away. True, a few years will not show much decay, but in the long future the result will certainly be disastrous. The constant action of the atmosphere, the expansion and contraction consequent upon extremes of heat and cold, and the disintegrating effect of rain-water, slowly but surely tell upon the integrity of the exposed parts.

The invitation extended to visitors to the Toronto Industrial Exhibition by the Gurney Foundry Co., to visit their extensive show rooms on King street west, and inspect their Oxford boilers and radiators, and other heating appliances, drew a large number of visitors to their establishment during the Fair.

A new kind of insulating and non-conducting material for covering heating apparatus, etc., consisting of flakes of mica, enclosed between covers of wire netting and canvass, forming mats of any size or shape, has recently been placed on the market by the Mica Boiler Covering Co., of No. 2 Bay street, Toronto.

The high price of hard wall plasters heretofore has prevented the adoption of them generally in Canada. The Alabastine Company, of Paris, Ont., announce in another column their "Paristone Wall Plaster," which they claim to be superior to anything now on the market, and at a price within reach of all. Architects who are interested in bringing the cost of buildings within the amount of their estimates might do well to investigate this new plaster. Situated as they are near to the central Canadian cities, and having their own mills and mines, it would seem that this firm might be able to produce the goods at a low price. The agency for this city has been established with the Toronto Salt Works, 128 Adelaide street east.

TESTING STRUCTURAL MATERIALS.

THE following are the subjects which appear on the program of an international conference, at Zurich, Switzerland, to be held on September 9, 10 and 11, to consider the adoption of standard uniform methods of testing structural materials. The conclusions of the conference will be watched with interest by architects and builders all over the world.

1. Future promotion of uniform methods of testing materials and important technical products.
2. Establishment of uniform methods of testing rust-preventing processes.
3. Relation of chemical composition of natural stones and their resistance to climatic changes; influence of smoke and sulphuric acid upon stones.
4. Method of determining quality and climatic resistance of roofing slates.
5. Methods of securing normal consistency and uniform density of cement test briquettes.
6. Investigation of methods of determining the constancy of volume of hydraulic cements.
7. Quick methods of determining quality of cement.
8. Adhesive strength of hydraulic mortars.
9. Technical value and physical tests of puzzolanas.
10. Investigation of anomalous phenomena of cements, especially of time of setting.
11. Investigation of influence of fecal matter on hydraulic mortars.
12. Processes of testing ordinary wrought iron, uniform methods.
13. Comparative tests, most simple measurements and expressions for flexibility of metals.
14. Influence of corrosion, wire tests for corrosion,
15. Tests of microscopic structure of metals, uniformity of methods.
16. Investigation of effect of very low temperatures on wrought iron.
17. Experiments on solder and soldering.
18. Compression tests of iron.
19. Cast iron tests.
20. Tests of iron and steel railroad material, axles, tires, &c.

Our Exclusive Business

IS THE HEATING AND VENTILATING OF ALL CLASSES OF BUILDINGS

OUR "ECONOMY" FURNACES AND COMBINATION HEATERS

combine the great essentials of a satisfactory heating apparatus, viz.: Economy in fuel, Simplicity of Construction and Ease of Management, Efficiency, Weight and Durability . . . . . .

In Combination heating—with hot water or steam—our position is pre-eminent. Our Company ORIGINATED and perfected that class of heaters, and the numerous attempted imitations of our Combination Heaters only serve to emphasize their superiority . . . . . .

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 10. OCTOBER, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this Journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

WHILE the present number of the ARCHITECT AND BUILDER is being printed, the American Institute of Architects is meeting in annual convention at St. Louis, Mo.

The Royal Institute of British Architects has raised a fund and secured facilities for the thorough testing of bricks and brickwork. The work will shortly be entered upon.

THE recent mishap to the conduit pipe of the Toronto waterworks should have a tendency to popularize the electric elevator, resulting as it did in stopping the operation of every hydraulic elevator in the city.

A MONUMENT is to be erected in Quebec to the memory of Samuel de Champlain, whose name is so intimately connected with the early history of Canada. Artists, sculptors and architects are asked to send in plans, models or drawings up to Jan. 2nd, 1896. The cost is not to exceed $30,000.

"THE manufacturers make more nails every year than can be sold," a Montreal manufacturer gives as the justification for a pool which has just been formed by the nail men in Canada. Combines among nail manufacturers have been in existence in the United States for years, but this is the first time, so far as we know, that a united move to diminish the output and increase the price has been made in this country. How long will it last?

IF the amount of building in a city is an evidence of prosperity, and no doubt it is, Chicago must be enjoying a return of good times. During May, June, July and August permits were issued for the erection of 3495 buildings, with a frontage of over 17 miles. The cost will reach $20,000,000. In 1894 permits were issued for the same four months to the amount of $11,539,065 and in 1893 for $7,638,455. The Windy City seems to be growing.

A POINT of considerable interest to contractors in Toronto is said to be likely to come up for decision at an early date. At the solicitation of the Trades Unions of the city, the Toronto Public School Board recently placed a clause in its specifications for work on public school buildings, providing that the contractor must pay his workmen the union rate of wages. On a recent contract, the contractor made an agreement with journeymen bricklayers to work at 30 cents per hour. It is reported that notwitstanding this agreement, these workmen propose to bring an action to compel the contractor to pay them at the rate of 36 cents per hour. Thirty-six cents was the rate which obtained under the recent agreement between the Bricklayers' Union and the Toronto Builders' Exchange. It will be remembered that this agreement lapsed on the 1st of May last, and the contractors contend that since its termination there has been no recognized scale of wages for journeymen bricklayers. This is the point upon which the decision is likely to turn should the matter be brought into the courts, and the outcome will be looked for with interest.

ACCORDING to a recent decision of the Court of Appeal in New York, builders of fire escapes are legally responsible for loss of life or limb which may arise from defects in their construction. In the case under review, a man while escaping from a burning factory was scorched by the flames issuing from a window and lost his footing, falling not on the platform of the escape, but to the ground. The Court held that the escape was not so constructed as to afford a safe means of retreat, and awarded damages.

THE galleries of the Parliamentary Library at Ottawa are floored with semi-transparent glass, which has the effect of shedding downward natural light in daytime, and upward artificial light at night. The Chief Librarian, Mr. Griffin, is of opinion that it is the material best adapted for the purpose. The problem now confronting the Librarian and Parliament is how to meet the requirements for increased accommodation without impairing the architectural beauty of the building. The only road out of the difficulty seems to lie in the direction of an additional and distinct building.

MR. Joseph Neilson, a well known engineer and railway contractor, of London, England, was in Toronto recently, and paid the city quite a compliment on the excellent condition of its streets. Nor is it the first compliment of the kind which Mr. Neilson has paid Toronto, for after a previous visit in 1868, and seeing our wooden block pavements on plank foundation, he offered to lay a similar pavement in London. The offer was refused, but subsequently block pavements on concrete foundations were adopted. In the moist climate of England asphalt is so slippery as to cause serious disadvantage. Jarrah wood from western Australia, which is very dense, is being substituted for pine and asphalt.

A WRITER in Architecture and Building puts in a plea on behalf of high buildings, but he seems to look at the matter largely from a selfish standpoint. He professes not to understand the agitation which has arisen against these huge structures—scientific monuments of the resources of our times, as he calls them—and condemns in no measured terms the enactment of laws against them. As we understand it, the agitation is based largely on sanitary grounds. A street lined with sky-scraping buildings can get little sunlight, and sunshine is a necessary requisite to health and comfort. It does not seem strange, to our way of thinking, that there should be a revulsion against these towers very early in their history.

IT is undoubtedly to the interest of the architect to seek a wide acquaintance in the community where he resides, as upon the number and character of his friends, combined with his own individual ability, will depend the volume of his practice. Attention has recently been directed to this phase of architectural practice by the fact that a commission has very unexpectedly reached a Toronto architect from Christiana, Sweden, to prepare plans for three dwellings of American type to be erected in that city. The client is a Swedish gentleman who for a couple of years occupied a position in one of the Toronto banks, but afterwards returned to his native land, accumulated money, is about to marry, and wishes to enjoy the comforts which the domestic architecture of Canada affords.

IN designing their buildings architects should endeavor to keep out of ruts. It is not unfrequently possible to distinguish the architect of a building by a single feature of design to which he has become partial, and which he has repeated over and over again in his practice. The writer has in mind a certain style of turret, the favorite of a certain architect, and which may be seen adorning the corners of half a dozen new residences, all within a quarter of a mile of each other. Because an architectural feature has been found to look well in a certain position is not sufficient reason for its unlimited reproduction. By working thus in a groove, architects are standing in the way of variety of architectural expression, and helping to perpetuate the monotony which marks to too great an extent the appearance of many of the business and residential streets of Canadian towns and cities.

WHEN we read in foreign architectural journals accounts of the conventions of the National Associations of Builders of the United States, Great Britain and Australia, we are led to wonder to what may be attributed the entire absence of organization on the part of Canadian builders and contractors. Are the conditions here so nearly perfect that there is nothing in the nature of reforms to be considered, either in methods of construction or as regards the relation of the building trades to other branches of business, or are the builders of Canada behind the times in the matter of organization?

A USEFUL little pamphlet entitled "How to construct and equip mills, factories and warehouses as fire hazards," has been issued by Messrs. Scott & Walmsley, fire underwriters, of Toronto. The authors regard fireproof construction as impracticable, but suggest means to bring about slow combustion, and facilities for extinguishing fires. Special stress is laid upon the danger of hollow spaces in walls, roof and floors, where fire may lurk unobserved, and which it is difficult to reach when discovered. If builders would follow the suggestions contained in this useful little work fires would be of less frequent occurrence.

THE rapid increase in the use of concrete for sidewalks, floors and other like purposes, has caused an unprecedented demand for cement. A large proportion of the cement is imported from England, Germany and the United States, but there is no reason why more should not be manufactured in Canada. We have the raw material, and a little capital and enterprise would keep some of the money at home which is now sent abroad. The main difficulty is that extensive experience is required, and that kind of experience which can only be acquired on the spot, for material from which cement is made varies greatly in quality, and unless properly worked the output is very liable to be inferior.

PARIS has hitherto been supposed to possess the largest theatre in the modern world, though our ancient friends could outdo us in this respect. But Ichabod, the glory has departed from the gay French capital, and the largest city in the world now possesses the largest theatre. It was opened in London, at Earl's Court exhibition, on August 31st. The building is 417 feet long and 220 feet wide, and the height of the roof 117 feet. The stage is 315x100 feet, large enough surely to accommodate any company. There are nearly 5,000 seats, and being without pillars, the view is good from nearly all of them. We are not told about its acoustic properties, but presume they are as perfect as can be secured. Compared with the Massey Hall in Toronto, this new theatre has considerably greater accommodation, the Massey Hall having seats for 3,500 in front of the stage.

IN the last number of the ARCHITECT AND BUILDER we referred to the by-law in force in Toronto restricting the area of certain classes of buildings to 4,000 feet, and the way it is ignored. Since then the matter has come before the City Council, a movement having been made to repeal the by-law. Ald. Shaw, Chief Graham, of the fire department, and Mr. Coatsworth, City Commissioner, went to Buffalo to inspect certain fire appliances, and took occasion to visit some of the departmental stores, where they found that there was no restriction, one shop there having an area of 32,900 feet. When they returned they recommended the repeal of the by-law, which recommendation the Fire and Light Committee passed on to the Council with its approval. But the architects of the city rose in arms, and when the matter came up the Council referred it back, so that the restriction continues in the meantime, but parties who have violated it will not be prosecuted. Our opinion remains unchanged. If an unlimited area is wanted the building should be made fire-proof. It is not right that any one should jeopardize his neighbor's property. Immense floor areas, filled with inflammable materials, whether goods in a departmental shop, or oil or other material in a factory, are hazardous, and the by-law is founded on a just conception of the situation We do not need to follow the example of Buffalo or New York in this matter

IN connection with improvements which are being made to Queen Victoria School, Toronto, Mr. Thos. Cruttenden, the contractor for the brickwork, was recently charged, at the instance of some of the workmen on the job, with having used inferior material in the construction of one of the walls. The Public School Board employed Mr. Siddall, architect, to examine and report upon the work, and his report entirely exonerated the contractor. The charge is alleged to have been prompted by spite on the part of some of the workmen who had been discharged on account of their irregular habits. Notwithstanding the annoyance and loss to which the contractor has been subjected, as the law stands at present he has no redress. He might bring suit for damages against the workmen who incited the charge, but the chance of securing compensation from such a quarter would be so extremely doubtful as not to justify proceedings on that line. Thus it appears that contractors are at all times in danger of being injured in reputation and put to financial loss whenever it may suit the purpose of an unscrupulous employee to fabricate a charge against them. It would seem but right that the law should be so amended that spite work of this character would be punishable with imprisonment.

THE ivy plant, which for centuries has lent attractiveness to the towns and cities of England, has within the last decade come largely into prominence in some parts of Canada, more particularly perhaps in Toronto, where in certain residential localities it may be seen clinging to the walls of almost every house. Judiciously employed, it greatly enhances the beauty of residence thoroughfares, but it should not be allowed to obscure the architectural beauty of our buildings. It is difficult to discover the wisdom of erecting costly buildings, displaying wealth of carving and other interesting features, to be hidden from view in a few years by the luxurious ivy. An English writer declares that there is no ground for the opinion which many persons hold, that ivy is a cause of destruction to buildings and of injury to the health of the occupants. On this point he says: "So long as such opinions prevail it cannot be too often repeated that the attachment of ivy to walls is an advantage altogether. If the walls are damp before the ivy is planted, the damp will disappear as the ivy overspreads their surfaces. If the walls are dry to begin with, ivy will keep them so by a double action, for should dampness occur through some accident, the ivy will suck out the moisture into its own substance, and in the event of driving rains, that occasionally act with force on walls, the imbrication of hard leafage will prevent the access of rain to the structure, and thus ivy is not only a remover, but a preventer of damp. As regards the integrity of the structure, however, the case is less clear. Fissures in walls clothed with ivy will sooner or later be discovered by the plant and filled up, and then mischief may be expected. When a shoot or root pushes through a fissure in the wall, and is left undisturbed, its natural growth soon begins to tell upon the structure. As the little nut tree carried the millstone, so the slender shoot of ivy will, by increase of girth, begin to push against the sides of the fissure, with the certainty of increasing it, and the probability of bringing the wall down. But where the wall is sound it is exposed to no such danger. Ivy does not make fissures, however quick it may be to discover them where they already exist. It follows, therefore, that, as a rule, ivy may be regarded as defending against time and accident, the walls that afford it support."

AN ARCHITECT'S VIGOROUS INDICTMENT.

WE are in receipt of a copy, in pamphlet form, of the address of Mr. C. Baillargé, C.E., etc., delivered before the Quebec Association of Architects, on the occasion of his vacating the presidency at the recent convention of that body. It bears the somewhat pretentious title, "Bribery and Boodling, Fraud, Hypocrisy and Humbug, Professional Charges and Pecuniary Ethics," and is a scathing indictment of the methods practised by some contractors and others to swindle the public and line their own pockets. We should be sorry to think that the practises Mr. Baillargé condemns prevail to any great extent—that they did would shake one's faith in the goodness of human nature—but we fear he is speaking by the book, and that in his city (Quebec) and province there has been far too much boodling and bribing in connection with contracts. Nor would we forget that recent events have shown that we cannot cast a stone at our neighbors in this respect. Mr. Baillargé's words of warning are therefore well timed, and though somewhat too forcibly expressed in places, and partaking to some extent of a personal character, should have the effect of putting architects, and others who heard them, on their guard against such practices. Want of space prevents us giving extracts, but we must express our appreciation of Mr. Baillargé's boldness in dealing with such a subject.

THE SIMPSON DEPARTMENTAL STORE.

THE Simpson building, now towering up at the corner of Yonge and Queen streets, in Toronto, taking the place of that destroyed last January, presents some unique features, which render it interesting from an architectural point of view. During the Industrial Exhibition, when its large iron skeleton stood out, without any covering, it attracted much attention, and few visitors passed without stopping to gaze on a structure, the like of which many of them had never before seen.

The building is considerably larger than the one whose place it takes. It covers an area of 118 feet on Yonge street by 157 feet on Queen street, with an annex 24 feet square on the south west corner, extending in the rear of the buildings on Yonge street. It is six stories high besides the basement, so that the total floor area, most of which will be utilized for selling goods, amounts in all to nearly 134,000 square feet.

The building is practically indestructible by fire. Should a conflagration occur in any flat among the goods, it can easily be confined to that flat, and the building itself would not burn. Stand pipes will be provided on every flat, with hose, available at all times. So-called fireproof buildings have shown that they are not such in great conflagrations. The iron beams and columns which enter into their construction will not burn, it is true, but they warp and twist with the heat, being thereby rendered useless, while their removal becomes all the more difficult and expensive. Measures have accordingly been taken in this building to fireproof the iron, if such a paradoxical expression may be allowed. The outside columns and beams are covered with stone and brickwork, those within are enclosed in concrete. Boxes were erected around the uprights and the concrete poured in, the boxes being removed when it had set. The beams are covered with slabs of concrete, and the joints will be filled with the adamant plaster put on for finish. This is a new method of fireproofing such a building, introduced into Canada for the first time. The work is being done by a firm in Pittsburg, Penn. The spaces between the floor beams will be filled in with hollow blocks of concrete, and on these the floors will rest. They will be of hardwood, and in the event of fire would only char, even if not flooded with water. The shelving and counters will of course be of wood.

The fronts of the first and second stories, facing on the two thoroughfares, will be filled in with plate glass. The four upper stories are of brick, built on to the iron frame. The rear walls are of solid brick, thick enough to resist any attack by fire from the outside. The roof will be of concrete blocks covered with felt and gravel.

The total weight of iron in the skeleton of this great building is about 3,000,000 lbs. The girders were prepared at the Hamilton Bridge Works, and had only to be assembled and riveted together when brought on the ground. So rapidly was the work done that in seven weeks from the time the first column was set the iron work was completed, and 13 or 14 weeks will see the building closed in ready for the inside finish.

The cost of the building will be in the vicinity of $250,000, and it shows what the departmental shop has become when Toronto can afford such a palatial structure in the retail trade.

Messrs. Burke & Horwood are the architects.

A nail combination has been formed which includes all Canadian manufacturers, and prices will likely be advanced.

THE City Council of Toronto will consider an amendment to the building by-law, to prohibit the erection of any dwelling house, on any street, lane or open space less than thirty feet wide, and providing that every dwelling house must have at least 300 square feet of land attached to it on which no building is maintained.

TORONTO CITY ENGINEER'S REPORT.

THE annual report of the Toronto city engineer for the year 1894 has just been distributed, and forms quite a bulky pamphlet. It contains full and complete information respecting the public works carried out during the year under review. A reference to some of the points brought out will be of interest.

We have had recent evidence of the extent to which the source of our water supply may be affected by the sewerage of such a city as Toronto. Perhaps it is not to be wondered at when we consider that 227¾ miles of sewers are constantly pouring their filth into the bay. It cost $5,146 to flush 112½ miles of sewer, a rate of $45.70 per mile, a reduction from $59.65 per mile the previous year. An extension of 2.67 miles of sewer costs $12,964.89, nearly all being built by contract. Private drains to the number of 489, making a mileage of 2.06, were also constructed from the main sewers to the property line.

The plumbing department made inspections to the number of 8,000. The number the previous year was 14,605, the falling off being doubtless due, in a large measure, to the restriction in building operations.

The question of roadways is and always will be an important one in Toronto. To find a paving material which will stand the traffic and resist the effect of climate, and at the same time not prove too expensive, has puzzled engineers and city councils everywhere. Asphalt seems to best meet the two first named requirements, but it is an expensive pavement, and has not therefore come into general use. If vitrified brick could be supplied at a cheaper rate it would without question be extensively used, and it will, we think, be one of the principal pavements of the future; but at present it is nearly as expensive as asphalt, and therefore cedar blocks, despite the objection to them on sanitary grounds, continue to be largely employed. The amount of new pavements laid last year was 8.15 miles, divided as follows:

Asphalt	3.067 miles.
Stone Setts on Concrete	2.563 "
Cedar Block on Sand and Plank	0.852 "
" on Concrete	0.826 "
Brick Setts	0.787 "
Scoria, Tamarac and Cobble	0.060 "

The total length of streets in the city is 253.48 miles, with roadways as follows:

Cedar Block	111.16 miles.
Macadam	35.95 "
Asphalt	13.70 "
Cedar with Asphalt on R. R. track	6.35 "
" " Brick " "	4.50 "
Stone and Scoria	0.81 "
Macadam with Stone Setts	0.54 "
Wood on Concrete	0.49 "
Unpaved	79.98 "

It will be observed that cedar blocks, which were put down so extensively a few years ago, still lead by a long way, though rapidly going out of favor. In 1890 there were fifteen and a half miles of cedar block pavement put down; in 1894 less than one mile. There are, however, over 24 miles of cedar blocks on which the time for payment of the local improvement tax has expired, which are in a bad state of repair and require to be renewed. This the engineer recommends should be done. Poor roadways mean a heavy tax for repairs and cleaning, to say nothing of wear and tear of horses, harness and vehicles. The strength required to haul one ton on a smooth pavement is between 16 and 20 lbs., on a broken stone road it is 60 lbs., and on a cedar block pavement in bad condition, from 100 to 150 lbs. That means that four or five horses are required to do the work that should be done by one. This aspect of having bad pavements does not perhaps present itself to the average mind with sufficient force.

As compared with other cities, Toronto's percentage of paved streets to the population shows up well. The following are the figures in a number of the leading cities:

	Per cent.
Toronto	68.5
Louisville	53.5
Buffalo	43.8
Detroit	41.8
Rochester	35.8
Jersey City	35.1
Kansas City	31.4
Milwaukee	12.6
St. Paul	11.9

But although Toronto has 54¼ per cent. of its streets paved, after deducting what is covered with cedar block there is only 10½ per cent. with anything like a durable covering.

As to sidewalks, during the year 1.148 miles of concrete and 18.03 of plank sidewalks were constructed. A small section of brick has been laid down on Gerrard St. East as an experiment. If it proves satisfactory brick will be more largely employed in the future. The mileage of plank sidewalk built has decreased each year since 1890, in which it was nearly 58 miles, showing that wood for sidewalks, as well as roadways, is rapidly going out of favor.

The asphalt pavements are kept clean on what is called the "orderly system," and it is carried on from May 1 till December. The cost is $1,236 per mile for the season. On the other streets the cost is $22.76 per mile. 59,172 loads of scrapings were removed.

The disposal of the waste of such a city is a serious matter. 103,333 loads of garbage were collected, of which 26,665 were consumed in the eastern and western crematories. A large quantity was deposited on the extension of the Esplanade on the water front. The removal of ashes and garbage from the outlying sections is now done by trolley car.

On the streets where railway tracks run the track allowance is watered by tanks mounted on trolley cars. Three such cars perform the service, for which the Railway Co. is allowed 65 cents per mile for the double track, sprinkled four times daily. The tanks hold from 2,500 to 2,800 gallons each. The company was paid for this service $1,972.42.

Mr. Ellis, the assistant engineer in charge of roadways, goes more fully into the question of brick pavements in his part of the report. In deciding on the best brick for the purpose, tests are applied for abrasion, absorption, crushing and transverse strength. Results are satisfactory as to our Canadian bricks, but the price rules them out. The lowest price quoted is $16 per 1000 for Canadian bricks, while in the United States they are laid down for $8.50 per 1000, and in some cases for less.

Mr. Ellis also gives some interesting facts as to the effect of water upon asphalt pavement, the latter sometimes rotting if the water is allowed to remain on it for any length of time, to such an extent that a knife may be inserted as far as the concrete. The cause of this is the destruction of the petroline, or bitumen, which becomes changed by oxydation into asphaltine, a substance resembling coke and of no value as a cement. Trinidad asphalt proved itself to be possessed of the greatest tensile strength. The concrete foundations of the asphalt pavements have stood the test well, in some cases having supported the roadway, under heavy traffic, where the earth had washed away below.

A somewhat curious and interesting test was applied to ascertain the effect of good roadways on the traffic. A census of travel had been taken on Yonge street in May, 1890, when it was block paved and in a very indifferent condition. The census was repeated in August, 1894, when it was asphalted. Though the number of street cars had increased from 818 to 1178 daily, the effect of which would be to drive ordinary vehicles to other streets, the average number of tons per day for each foot in width of roadway increased 24 per cent., or from 59.15 tons to 73 tons, and this notwithstanding a considerable decrease in the number of vehicles, proving that good roadways conduce in a very marked degree to economy in transport.

The report, which shows great care on the part of Mr. Keating in all that pertains to his department, contains much valuable information respecting works of construction in such a city as Toronto. The above references will give some idea as to the information it conveys.

PERSONAL.

Mr. James Snoddy, of Snoddy & Bros., plumbers, Hamilton, died last week.

Mr. Samuel Edger, secretary of the Owen Sound Portland Cement Company, died suddenly at that town on Sept. 23rd. He was 50 years of age, and an old resident.

Mr. James Herbert Marling, a talented young architect, who began his professional career in the office of Messrs. Darling & Curry, Toronto, died recently of apoplexy at Buffalo, N. Y.

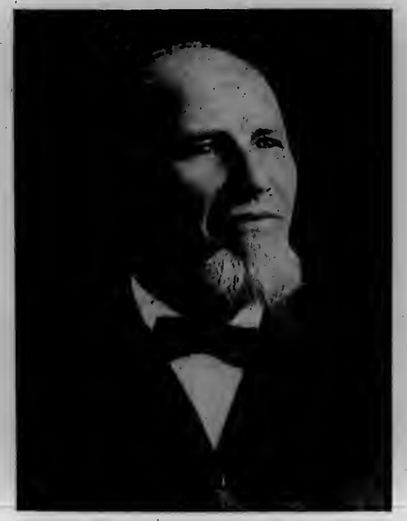
It is with much regret that we have to record the death of Mr. L. M. Bowman, who was formerly in practice as an architect at Lindsay, Ont., but latterly held a position in the Medical Health Department of Toronto.

MR. A. C. HUTCHISON, R.C.A.

ALEXANDER Cowper Hutchison, R.C.A., was born in Montreal in 1838. His father was a builder, and in company with James Morrison, erected some of the principal buildings in Montreal. Mr. Hutchison, after leaving school, entered as an apprentice to his father as stone cutter, also attending a private school during the first two years of his apprenticeship. At the age of twenty he was entrusted with the superintendency of the stone work of Christ Church Cathedral, known to be the finest example of Norman Gothic on the continent. He afterwards removed to Ottawa, where he was engaged for three or four years on the Parliament Buildings, in charge of the stone cutting. He then left the capital and returned to Montreal to take charge of drawing classes in connection with the Mechanics' Institute. He afterwards conducted the same classes in connection with the Board of Arts and Manufactures, and while engaged at this work he decided to commence practice as an architect in 1863, and soon secured a large practice. He was appointed a member of the Royal Canadian Academy by the Marquis of Lorne in 1880.

THE SIZE OF WINDOWS.

IT seems a self-evident proposition, yet one that is continually disregarded, says Aston Webb, that the size of the windows must be regulated by the size of the rooms that they are intended to light, yet nothing is more common than this example, where three windows all of the same size, "to preserve the uniformity of the elevation," as the speculative builder says, light three rooms of totally different sizes, the result being that one bedroom is fairly lighted, the other is very dark, while the dressing-room is so light that you hardly dare dress in it without the blind being drawn down, as you seem to be quite out in the open air. It is extremely difficult to lay down any law giving exact rules as to the proportion of lighting space necessary for a given room—much depends, for instance, on the position of the light. In the well-known example of the Pantheon at Rome the building is amply lighted by a small circular opening in the roof. The cubic contents of this building are given at 1,934,460 cubic feet, and the area of the circular opening only 572 feet, or about one-third the amount required had the lighting been from the side. The rule said to have been adopted by Sir William Chambers is to add the depth and height together and an eighth of the result will give the width of the window. Gwilt gives, as a general rule, 1 foot super. of light in a vertical wall to every 100 cubic feet in the room. Robert Morris says that the superficial area of the window should equal the square root of the cubical contents of the room. This, however, though no doubt approximately true, must evidently be open to large variations according to the width of the street, and especially according to the aspect and the climate, and the exact size of certain windows to suit certain shaped rooms can only be learned by observations and experience. It should also be borne in mind that certain rooms will require more lighting than others: a drawing-room more than a dining-room, a dressing-room more than a bedroom, and so on. And if this is carefully attended to (and, of course, taste and discrimination used), the elevation will at least be an honest and truthful one, and you will not find the principal window on the ground floor lighting, as is often the case, a cloak-room or a water-closet.—Carpenter and Builder.



MR. A. C. HUTCHISON, R.C.A.
President Province of Quebec Association of Architects.

MONTREAL.

(Correspondence of the ARCHITECT AND BUILDER.)

THE Canada Life Assurance Company's building, the most important building being erected in Montreal this year, is fast approaching completion. The contractors certainly deserve praise for the celerity with which they have conducted their work, affording a remarkable contrast to the slowness of completion of the unfortunate Street Railway Company's building, the structural iron of which is not even yet completed, although it was commenced long before the first named structure.

As the roof of the Canada Life Building is now being put on, it is safe I think to indulge in a few comments regarding it, as what remains to be done will not materially alter its exterior appearance. It is another proof of how an inferior design can be made to look well, and the influence it may have on the decision of unprofessional judges in competitions, when it is effectively rendered in perspective by an artist.

I hear that designs much superior in composition to the accepted design were submitted by Montreal architects in private competition, but unfortunately their authors overlooked the absolute necessity of rendering their drawings brilliantly and effectively in order to be successful under the circumstances.

In the upper storeys there are faults violating the most elementary rules of art, as, for instance, the idea of superposing two rows of columns on top of one another, with the lower row much thinner and weaker in construction, and more delicate in design than the one above.

The mouldings, although good enough in profile, are so placed and arranged as to make the building appear to have been erected in sections, and the parts present no relation to one another. The doorway is also much too low for a building of such importance. Altogether the design does not reflect any more credit on the architect than the Ontario Parliament Buildings, and it certainly does not seem to be necessary to look outside of this country for architects to design our most important buildings, if the public feels satisfied with such architecture.

An exhibition exclusively confined to artists and works of art will open in the Drill Shed on the 14th inst., for the benefit of Notre Dame hospital. Most of our painters in this province are represented, but unfortunately the architects did not see fit to avail themselves of the opportunity to bring their work before the public, which, I believe, is the only and surest way of elevating the architectural profession to the level of that of the painters in the eyes of the public. Artists across the ocean have gained their prominence by exhibiting their work constantly before the public, and by establishing permanent exhibitions; we must do likewise if we desire that art in all its branches be as honored and respected as it is in the old countries. Apart from the paintings are quite a number of water colors, but the architectural section will be represented only by "A Vestry," a school "projét" of the "Ecole des Beaux-Arts," by J. O. Marchand, who exhibits also a water color representing a racingyacht.

Messrs. Patterson & Wallace, architects and engineers, 217 St. James street, announce their intention of opening evening classes, in which students of architecture and engineering may receive instruction in drawing, mathematics and designing.

The Toronto Radiator Manufacturing Co. are said to have sold in one week in New Brunswick one hundred and ninety-five radiators.

Mr. D. L. Brown, formerly of Deseronto, Ont., has the contract for building a large school house at St. Johnsville, N. Y.

A new City Hall is being built at Quebec to cost $117,000. Sixty thousand dollars have already been expended, with only $130 for extras.

A quarryman named Fairweather has brought action against the Owen Sound Stone Co. for $10,000 damages, sustained by him when working for the Company. He was drilling out a charge when it exploded, causing the loss of his eyes. The case was tried once, but a new trial has been ordered.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE fifth annual meeting of the Province of Quebec Association of Architects was held in the city of Quebec, as announced, on the 2nd instant, at the "Chateau Frontenac." The morning session opened at 10:30 o'clock, at which were present the following members: Messrs. Chas. Baillairgé, President, in the chair; A. C. Hutchison, 1st Vice-President; A. T. Taylor, 2nd Vice-President; J. Venne, Secretary; J. Perrault, Treasurer; J. Nelson, R. Findlay, F. X. Berlinguet and J. B Bertrand, Councillors; and also S. Lesage, H. Staveley, J. F. Peachy, J. P. S. Dussalt, G. E. Tanguay, J. P. Ouellet, Geo. Bussières and D. Ouellet.

The President having taken the chair, the Secretary presented his report for the year just closing, which in substance is as follows:

SECRETARY'S REPORT.

"The Council of the Province of Quebec Association of Architects presents to the Association the following report of its transactions during the year 1894-95:—

The architectural exhibition held in connection with the last annual meeting, although quite an innovation, was attended with signal success, and we can only recommend that annual exhibitions of architecture, and perhaps in connection with arts and crafts, be held under the direction of the Association.

The most important work of the year has been the revision of the building by-laws for Montreal. A committee was appointed consisting of the following members: Messrs. A. C. Hutchison, A. T. Taylor, J. Nelson, A. Raza, J. Venne, J. Perrault, J. Z. Resther and W. E. Doran. This work has been completed and submitted to the City Council in last April, and has lately been returned to our Council for the revision of the French translation made by the civic authorities. It required over sixty meetings to complete the work, and we have good reason to believe that if these building by-laws are passed in Council, which we trust will be done, they will be an immense improvement on the previous ones, and be of great benefit to everyone concerned, and to the city.

The library is increasing slowly, and we beg to acknowledge donations from Messrs. Chas. Baillargé, A. T. Taylor and J. Venne. Twenty-five volumes have been handsomely bound during the year, and it is intended to supply each member with a catalogue of all the books in the possession of the Association within a reasonable time.

We regret to report that notwithstanding the trouble taken by the Council and the correspondence with the Government, that the question of the Schedule of Charges is not much advanced. There being two alternatives presented by the Government—first, an arbitration to decide upon the items of charges and the opportunity to make them obligatory by law, the Association paying all the expenses; the other, and that which seems to be preferred, is that the Association shall issue said schedule and force it into use, and that it shall become law by long and united usage. What arises from all this is that the profession would gain enormously by a greater unanimity of action, for the common interests of all.

We think it is only due to ourselves that frequently foreign architecture are employed in the Dominion, especially in Montreal, Toronto and Quebec. It is not too much to assert that the Canadian Associations of Architects have amongst them able and distinguished members, who can compare advantageously with those architects who are confiscating work to which Canadians are entitled. It is time time to protest against a thing which has become an abuse, causing prejudice, not only to our profession, but indirectly to the whole country at large, in that it deprives a good proportion of the population—architects, mechanics, manufacturers, etc.—of their just rights. The Federal Government has done something in the matter by levying a custom duty on plans coming from abroad, but more is required.

Your Council has presented to the Montreal City Council a petition urging the organization of an Art Standing Committee, which should examine and report on all plans, designs and models of monuments and embellishments of our public squares and avenues. The adoption of this suggestion would not entail any additional expense to the civic treasury, and could do only good to the public in fostering the art feeling, which is rather weak. The City Council, having many vexed questions on the tapis, has apparently been unable to consider the proposal as yet, but it is hoped that it will soon do so.

At the winter examinations held in Quebec in January, four candidates passed successfully—three candidates were for preliminary examinations and one for final. At the July examinations held in Montreal four candidates presented themselves, all of whom passed.

The Association now numbers 63 members—11 from Quebec, 1 from Laprairie and 51 from Montreal.

For the first time since its foundation the Association elected honorary members, viz: His Excellency the Lt.-Governor of Quebec, the Premier and the Minister of Public Works, Quebec; the Mayors of Montreal and Quebec; Sir Donald Smith, the Hon. Geo. A. Drummond and Mr. R. B. Angus.

As a trial the Council invited a competition for designs of a seal and letter heading for the Association, and offered $10 as a first premium. Several designs were received, but were not considered fully satisfactory by the Council. It may not be out of place to impress on the members of this Association the advisability of inducing the governments and municipalities to have the designing of public buildings thrown open to competition to recognized architects—members of some Association of Architects, throughout the Dominion, under well defined and dignified rules. We feel sure it would tend to improve the standing of the profession and help to create a greater national interest in architecture. It may be advisable to have a special committee to consider the matter or to refer it to the new Council for action.

During last winter the Association had its usual monthly dinners and meetings. These meetings are capable of being made very pleasant and useful by interesting members in them. Papers were read by Messrs. A. C. Hutchison, A. T. Taylor and J. Venne.

Six members have requested the aid of the Council to solve some professional difficulties, and the Council gladly gave such aid as was possible.

The possession by the Association of a portrait of Mr. Chas. Barry, hung in their rooms, has inspired Mr. J. Venne to present one of Victor Bourgeault, a well-known architect of Montreal, who died just soon enough to deprive the Association of his services. The idea has been suggested that the Association should possess the portraits or some memento of the most eminent of its deceased members, to serve as a remembrance to younger members, and more especially to their old pupils.

We must before closing acknowledge the good-will of the press and their readiness to report to the public anything that was considered of interest during the year, transacted by the Association."

The report was unanimously adopted. The report of the Treasurer was also adopted.

The President read two letters, one from the Prime Minister and one from the Minister of Public Works, expressing their regret at being unable to attend the luncheon in the evening.

The meeting then proceeded to the election of officers and Council, with the following results:—President, A. C. Hutchison; 1st Vice-President, A. T. Taylor; 2nd Vice-President, J. F. Peachy; Secretary, Jos. Venne; Treasurer, Jos. Perrault. Council: C. Baillairgé, 1st member; R. Findlay, J. Z. Resther, A. H. Lapierre, G. E. Tanguay and Theo. Danust. Messrs. A. J. Fowler and C. Chausée were selected as auditors.

The newly-elected President, Mr. A. C. Hutchison, took the chair, and a vote of thanks, proposed by Mr. H. Staveley, seconded by Mr. J. F. Peachy, was passed to the retiring officers for their efficient services to the Association.

It was resolved to have a new official list of the members of the Association printed, containing also the names of the honorary members and those of the officers and Council at the head.

On motion of Mr. J. Venne, seconded by Mr. G. E. Tanguay, it was decided that steps be at once taken for the organization of an architectural exhibition and of the allied arts, in connection with the next annual meeting, and that the Council be authorized to take action in the matter.

Moved by Mr. S. Lesage, seconded by Mr. A. T. Taylor, and resolved, that the Association take the necessary steps to have the Augé Bill amended to meet the views of the architects, or to secure its repeal.

Mr. A. T. Taylor explained what had been, and what he would propose should be done in connection with the creation of an Art Standing Committee in Montreal, to advise the City Council regarding the selection of sites for projected monuments of public character, and the erection of the same, as well as the opening of new streets and boulevards, or things of similar character, relating to the embellishment of the city. The need of such a measure is to be observed in the old city of Champlain where action is necessary to preserve the few souvenirs of its glorious past that we have left. Several of the members of Quebec touched upon the subject in the same strain, and it was agreed that action be taken in the matter.

A series of amendments to the charter and by-laws were submitted by the Quebec section for consideration by the Council during the year.

Mr. R. Findlay submitted for consideration a standard form of contract for use between proprietor and contractors; the Council will report on same at next annual meeting.

The meeting adjourned at this point till 3:30 p.m.

AFTERNOON SESSION.

At 3:30 o'clock the members again met at the "Chateau Frontenac."

A paper was read by Mr. Baillairgé on "The Bearing and Resisting Strength of Structures," (printed elsewhere in this paper) and on "Bribery and Boodling."

Mr. J. F. Peachy urged that action be taken to make the tariff of charges recognized by the public, his remarks being followed by a discussion as to whether the architect should refuse work when the superintendence of same is refused him. The majority of the members were of opinion that when the architect is deprived of the superintendence he should be free of all responsibility.

It was decided on motion of Mr. J. Venne, seconded by Mr. A. T. Taylor, that the Council consider the advisability of a proposition which would have for effect inducing the governments and municipalities giving out their work by competition on a basis guided by proper rules prepared by the Council for the purpose, and that the Council be also authorized to communicate with sister societies to discuss the matter at as early a date as possible.

It was agreed that the examiners shall receive in future $10 each for their services at each examination.

It was proposed that the Montreal and Quebec sections organize in their own locality sketching classes for the use of the members, in the interest of their advancement, and with the effect of promoting fraternity

Mr. J. Venne took a retrospective view of the position in which the profession has stood during the last ten years.

It was moved by Mr. Geo. Bussières, seconded by Mr. F. X. Berlinguet, that the meeting be adjourned, and that the next annual meeting be held in Montreal at a date to be fixed by the Council, but preferably to fall in September.

THE LUNCHEON.

The luncheon given in honor of the visitors at the Chateau Frontenac was one of the best ever given in Quebec. The ladies' ordinary was handsomely decorated for the occasion. President Baillairgé occupied the chair, having on his right Mr. Hutchison, the new president, and on his left Mr. J. M. Lemoine, ex-President of the Royal Society of Canada. Mr. Berlinguet occupied the vice-chair. About thirty sat down to the well spread tables. After the toast of the Queen had been duly honored, Mr. Hutchison proposed the health of Mr. Baillairgé and the Quebec section, to which the retiring president made a forcible reply. After urging a strong plea for the retention of the French language, and condemning any scheme for the assimilation of the currencies of nations, their methods of computing time, or their weights and measures, all of which he asserted would have a tendency to reduce the demand for labor, he went on to express regret that the Montreal visitors could not remain longer with them, in order that they might make a return for hospitalities shown by that city at a former meeting. Addressing himself specially to the Montrealers he then proceeded:

"In your legitimate pride as metropolitans, you make little of us, Quebecers,—we are at the end of the world, and it is exceptional to find in your city press more than three lines at a time devoted to the doings of the olden capital. Our turn will come, and may be it is close at hand. If Quebec to-day is attractive to tourists only, due to its drives, its points of view, its terraces, the surrounding landscape, its unrivalled port, its carnivals of ice and fire—if commerce, business, have for 30 years past eschewed, abandoned our port, and rendered us disinterested to the extent of cutting our own throats to favor Montreal, to make it an ocean port, the head waters of ocean navigation, by spending our millions in deepening Lake St. Peter—nature is about to force you to return to your whilom loves—for apart from the Chicago canal, which will lower the St. Lawrence between Quebec and Montreal and up to Lake Ontario by fully 5 per cent.—and I was the first to call the attention of our people to this unwarranted, unauthorized international spoliation—apart, I say, from the tapping of our waters to draw them off towards the Gulf of Mexico—there are other schemes upon the tapis (the Deep Water Convention now being held at Cleveland is proof to what I say): canals, one or more, which will run another 10 per cent., another 20 of our noble river, from the great lakes towards the Atlantic by the Mississippi and the Hudson; and this handiwork of man is already being added to by natural causes; our waters as you see on all hands are being lowered, shallowed. Man is and has been the direful agent in bringing this about—he has, under our Government's most unwise policy of timber limits, with no reserve cut down our forests, left bare the ground, the country; instead of the wise policy of France and of the Mother Country, to cause the forest to persist, by sparing every tree less than twelve inches in diameter—he has swept the surface clean, and where the axe has been impotent to do the unhallowed work, man has abetted fire in its devouring greed to lay waste our God-given patrimony of wealth and plenty. Well, see you how it is? You are astonished nowadays at the greater frequency of cyclonic winds, and storms and inundations. No wonder, though this should be so, when the winter's snow, which formerly, protected from the sun's rays by the foliage, melted and ran off slowly into rills and rivulets and rivers; now melts, as it were, all at a bound of sunshine and rushes along in its maddened devastating course, carrying away mills and bridges and whole villages, and increasing our waters to a depth unknown before in spring; while per contra, the rains of summer which, when the lands were wooded, ran from them slowly and measuredly, as in the wisdom of God it had been willed they should, reaching in time our lakes and rivers through their tributaries, these waters now are sucked up by the sun, before they reach their destination, or on the way, absorbed by the dried up, parched beds of the unprotected rivers; and hence in every way the St. Lawrence is gradually growing less; and gentlemen you will have to come to us to get deep water; for, thank God, the Ocean is still there, and the moon far enough away from man in his destructive rage, and though he may bring it within a stones throw by the telescope, to be not able to interfere with it, much less the sun in giving us the tides which, if they connot reach to Montreal, will continue to Quebec, and make this the head of ocean navigation, the true ocean port for steamers of draught too great for shallowed Lake St. Peter. Now think ye, gentlemen, that we dote on these possibilities of the near future; think ye that we tell you this in proud retaliation of the past? Not so, by any means, we look forward to it with pleasure, to do you good, not harm; to help you find a remunerative field for your unexpended and ever increasing millions. Come to us, we are ready to receive you with open arms; we have for some years past been endeavoring to put on the new man—not the new woman with her unfeminine, unloveable prerogatives—we have a new parliament, a new post-office, new Courts of Justice, new hospitals, new hotels: the Florence, Clarendon, Victoria, and Chateau Frontenac, adequate to all tastes, all purses, all aspirations—we have a new city hall by our friends Tanguay and Vallée and a new Mayor full of youth, talent and initiative enterprise. He saw as I pointed out that the westward cry must be abandoned, and that instead of St. Sauveur, St. Roch or Mount Pleasant, the walled portion of the city was geographically the most central for Quebec's future, and now the extension of the city is going forward towards Montmorency, between which and the city proper there is a stretch of six or seven miles of unimproved territory. This is where we await your Montreal millionares, and we will not be jealous if they bring you down with them to build them up and tell them how to make available ground of the Beauport foreshore by building return tramways to the close by heights and quarries, where lie ready, centuries of quarry refuse which would reach its destination by gravitation only and the loaded cars return the empty ones. Ground can be made here for almost nothing. Gentlemen, this is no idle theory of mine—already some of your own people are here at work. Messrs. Whitehead & Co. have erected vast cotton and woollen factories at the Montmorency, and one of yourselves, Walbank, is the architect. The thriving village of Hedlyville is advancing to meet La Canardière and Richardson's factories. Messrs. Parent and Bedard, both ex-Mayors of the large and thriving parish of Beauport, have for the fourth time in nearly three centuries rebuilt the as often fired brewery of Racey memory and celebrity, the water from the river Beauport being pronounced by analysts amongst the very best in America for the required purpose. This factory of beer and lager will do much good in weaning men from their whiskeying propensities, it will render them stern and strong and healthy, and fit them for your purposes of building you up docks, elevators, refrigerators for your trans-atlantic business, while the want of water at Montreal may seriously impair the utility of your Hochelaga and other schemes. Once more then, gentlemen, let us say, come to us and we will receive you for our mutual benefit with welcome and outstretched arms.

A number of other toasts were given and responded to, after which the very pleasant gathering terminated.

Mr. S. G. Beckett, architect, 15 Toronto street, Toronto, would be pleased to receive samples of materials.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A CITY STORE FRONT.

THE competitions previously held under the auspices of the CANADIAN ARCHITECT AND BUILDER were especially designed to test the student's ability to properly design and plan various kinds of buildings. The object of the present competition is to test his knowledge of construction. It is to be feared that many students who have the ability to make pleasing sketches, are less proficient as regards a knowledge of the character of materials and the proper method of employing them in building construction.

With the object, as stated, of bringing to the proof the knowledge of this character which they may possess, students of architecture residing within the Dominion of Canada are invited to submit competitive designs for a city front for a retail jewelry store on a leading street.

The building is to have a frontage of 35 feet, and to be 5 storeys in height, with a retail store on ground floor, and a side entrance affording access to upper storeys, which are intended to be used for office purposes.

Drawings must be made with PEN and BLACK INK on WHITE cardboard, drawing paper or tracing cloth. On one sheet is required an elevation and plans of ground and first floors of the building, drawn to ⅛ scale; on another sheet, working details of ground floor, drawn to ¾ scale, and sufficiently coarse to admit of reduction to 15 x 10 inches in size.

Each competitor is required to mark his drawings with his nom de plume only, and to forward his drawings, so marked, post-paid, addressed to the editor of THE CANADIAN ARCHITECT AND BUILDER, Confederation Life Building, Toronto, at a sufficiently early date to enable them to reach their destination before 5 o'clock p.m. on the 3rd day of December next, at which time the competition will close.

Each competitor must forward with his drawings a sealed envelope, containing his nom de plume as it appears on his drawings, together with his full name and address, and a brief description of his design, stating the materials proposed to be employed in its erection.

The first premium in this competition is $10.00, the second $5.00, and the third one year's subscription to the CANADIAN ARCHITECT AND BUILDER.

The competition will be decided by a Committee of three members of the Ontario Association of Architects.

The CANADIAN ARCHITECT AND BUILDER reserves the right to publish any of the drawings submitted. All drawings will be returned to their authors within a reasonable time after the competition is decided.

Competitors are urged to pay strict regard to the above stated conditions. Drawings which do not conform to the conditions will not be considered.

DRILLING GLASS.

GLASS can be drilled with a common drill, but the safest method is to use a common broach drill. No spear-pointed drill can be tempered hard enough not to break. The broach can be either used as a drill with a bow or by the hand. It should be selected of such a bore that it will make a hole of the required size, about 1 in. from the end. It should be broken off short with a pair of pliers, at about 1½ in., and when the sharp edges are blunted by drilling, a fresh end should be made by breaking off ⅛ in., and so on, until the hole is bored. It is always desirable to drill from both sides, as it prevents the glass from breaking. Drill lightly and lubricate with spirits of turpentine and oil of lavender, or a little camphor instead of a little oil of lavender. Holes may be drilled through plate glass with a flat-ended copper drill and coarse emery and water. The end of the drill will gradually wear round, when it must be reflattened, or it will not hold the emery. The best means of drilling holes in glass is by using a splinter of a diamond. A brass drill is made to fit the drill stock, sawn down a little way with a notched knife to allow the splinter to fit tight, and the splinter fixed in the split wire with hot shellac or sealing wax. The drill is to be used quite dry and with care. If the hole to be drilled is wanted larger than the tool, drill a number of small holes close together to form a circle as large as the holes required: then join the holes with a small file.

USEFUL HINTS.

The French and English papers, which are now used, come without friezes, which is a distinct gain in the matter of height, while it possibly detracts from the breadth of a room.

It is with color as with every form of art, it can only be handled by those who delight in it. Bright, pure colors are the basis of richness and purity of hue, but their successful use demands a delicate handling of subordinate hues and tints.

Strong liquid ammonia mixed with an equal bulk of turpentine may be used with advantage in removing old paint. It is unnecessary to apply anything additional to the surface of the wood for repainting, as is the case when lye is employed.

In experiments conducted by the German government on steel and iron girders, the soft steel girder proved twenty-two per cent. stronger than the iron girder. The strength of steel girders appeared to be about the same for the flanges, if made alike in sections.

Paper that is difficult to remove, even by the application of hot water, should be given a coat of hot paste. The paste assists in preventing the water from running off the surface; it will soon soak through. In the case of varnished papers it is necessary to score the surface with a chisel.

Blue walls, or those with blue lights in the color, make a room seem large, as blue recedes from the eye. This color must be skilfully used, however, for if too pale it is cold and unsympathetic; if crude it takes all color from the complexion of its mistress. The shades of blue that wear the best on the nerves and senses are toned with grey, yellow or pink.

The wall papers shown in New York this season are said to be much darker, and, like everything else, show elaborate floral decorations. Even a black surface is shown, with garlands or festoons of gay flowers. Maroon is very effectively used; it forms such a pleasant background for pictures. Artists claim that the use of the very light papers of the past few years has detracted from artistic effects, and a return to more pronounced colors will greatly increase the richness and beauty of interior decorations.

It is not generally known that the word "Anaglypta" has a classical origin. To the ancient Greeks the "glypta" meant every variety of engraved wood, until at a later date cameo cutting became popular among them, and it became necessary to add to their vocabulary in order to define the new art. "Cameo" was, of course, raised work, as distinct from "intaglio" or incised cutting, and the "ana," meaning raised, was therefore added as a prefix to the preceding term, in order to express this meaning. Subsequently the word "Anaglypta" came into general use to describe every kind of bas-relief.

A cement for wet places, like aquariums, is made of litharge, fine white sand and plaster of Paris (calcined plaster), each 1 part, and resin ½ part. The ingredients should be thoroughly mixed and made into a paste with boiled linseed oil to which a drier has been added. It should then be thoroughly mixed by beating and allowed to stand four or five hours before being used. It should not stand much longer than this, as the cement becomes worthless after it has been mixed twelve or fifteen hours. Glass may be cemented to wood or metal with this preparation, and it will resist the action of both fresh and salt water.

The ancients, according to Palladio, first squared and worked the sides of the stones which were to be placed one upon the other, leaving the other sides rough. The edges of the stones, being beyond the square, were then smoothed. But the roses between the modillions and similar ornaments of the cornice, which could not commodiously be done when the stones were fixed, were carved upon the ground. If the works were very great, as the Arena of Verona, the Amphitheatre of Pola and other buildings, to save expense and time, they worked only the imposts of the arches, capitals and cornices; the rest they left rough. But in temples and other buildings which required nice work, they spared no pains in the execution, glazing and smoothing even the very flutes of the columns and polishing them carefully.

Chimney felling is an art little known. Mr. Smith, a Lancashire steeplejack, recently dispnsed of his forty-sixth tall chimney with ease and despatch, thereby forstalling the laws of bricks and mortar, which threatened a descent without Mr. Smith's assistance. It seems to be the easiest thing in the world. The stack has lumps of it cut out at the base, one side being left alone, and props are then introduced into the gaps, shavings, paraffin, and tar being liberally added, as the cookery books have it. When all is ready, a match is applied, the smoke of its own burning rushes up the chimney, and in a few minutes the whole thing collapses. The chimney, which was 135 ft. high, came down twenty-five minutes after the match was applied in the most docile fashion, and, what is more, it disposed its remains exactly as Mr. Smith, who stood close by, had arranged.

A solution of 50 parts of commercial alizarin in 1000 parts of water, to which a solution of ammonia has been added, drop by drop, until a perceptible ammonia odor is developed, will give to fir and oak a yellow-brown color, and to maple a red-brown. If the wood is then treated with a one per cent. aqueous barim chloride solution, the first named becomes brown, and the latter a dark brown. If calcium chloride be used instead of barium chloride, the fir becomes brown, the oak red-brown, and the maple a dark brown. If a two per cent. aqueous solution of magnesium sulphate be used, the fir and oak become dark brown, and the maple a dark violet-brown. Alum and aluminum sulphate produce on fir a high red, and on oak and maple a blood-red. Chrome alum colors maple and fir reddish-brown, and oak Havana brown. Manganese sulphate renders fir and maple a dark violet-brown, and oak a dark walnut brown.

THE LATE PETER THOMSON.

WE give in this issue a capital likeness of the late Peter Thomson, who, at the time of his death, occupied the position of superintendent of Algonquin Park, the reservation set apart in the northern part of the province, by the Ontario Act of 1893, as a preserve, to be kept in its natural state for the use of the people. Previous to entering the employ of the government, Mr. Thomson was in business as a building contractor. He learned the trade of a carpenter in his youth, and after living in the United States and Hamilton for a time, settled at Brussels, in the county of Huron, where he lived for some 35 years. While there he erected many buildings in the neighborhood. Removing to Toronto some years ago, he continued in the same line, the construction of the Arlington Hotel being one of his largest contracts. Since 1893 he was employed by the government on colonization road work, superintending the building of some of their bridges, and was always considered a careful and competent man for the work. In July 1893, he was appointed chief ranger of the Algonquin Park, and in the following year became its first superintendent. He died at headquarters in the Park, on 5th September, of paralysis, at the age of 61.

THE LATE PETER THOMPSON.

A LEGAL VIEW OF AN ARCHITECTS' RESPONSIBILITY.

A CASE of more than ordinary interest to architects was recently argued before a judge in the town of ——— Ontario.

An architect, a member of the Ontario Association of Architects, received instructions to prepare plans and specifications and obtain tenders for the erection of an hotel building in a country village. The owner, after the plans and specifications had been explained to him carefully, accepted tenders and instructed the architect to proceed with the work, and supervise it.

The architect being unable to collect his commission and having waited until the last day, caused a lien to be registered against the building for the balance of the commission and later, failing, still to get his money, entered suit under power of the lien for the balance due him.

The defense set up that as there was a defect in the building they were entitled to damages from the architect therefor.

There had been a building on the site which had been destroyed by fire and it was decided to re-use the old foundation walls as far as possible, the owner undertaking to clear away all debris and leave the walls clear for examination and work. This was all clearly set forth and shown in the plans and specifications, the latter stating that it was to be assumed that the foundation walls were in good condition and would only require to be pointed up. The owner urged upon the architect the necessity of getting the building ready for occupation with the utmost dispatch.

The defect referred to was a slight sinking of the floor in the centre of the building and showing in one of the principal rooms and the main hall, a condition which might have been brought about by the frost (the building was put up in winter) leaving the foundation wall, or by the wall plate under the partition never having been set level, or by the joists themselves never having been levelled properly. The amount that the floor was out of level was one thirteenth of an inch to the foot one way and about one sixth of an inch across. No plaster was cracked, no doors bound and no inconvenience of any sort was occasioned except that the apparent deficiency in the maple floor offended the refined eye of the defence. They also claimed that one riser of the steps from the street to the building was out of plumb, another serious defect.

The defence secured the services of an architect who swore to the levels which he had taken at the building and also to the riser being out of plumb, but could not say just how much.

A member of the Ontario Association of Architects was called by the plaintiff. He swore that he had visited the building and inspected it. He considered that the plans and specifications had been unusually well carried out for that class of work and that the deflection of the floor was scarcely sufficient to be called a defect in a country job.

The owner admitted in cross examination that he had got a first class job, but claimed that it would cost him so much to rectify the error and that the architect should allow him for it.

Two practical builders swore they had been in the building and never noticed the deflection. The mason and carpenter each swore that they had carefully levelled that part of the walls and floor and admitted that if there was anything wrong they were to blame, and finally the architect swore that he had levelled the ground floor joist himself when they were laid on and left them true and level. As for the riser—well there were many ways in which it might have got out of plumb after six months use.

The judge in summing up the evidence said that undoubtedly there was a defect in the building and he would give judgment for the plaintiff with costs, less a sum which it had been shown would be sufficient to raise the floor and make it level (?). He did not refer to the riser.

Virtually he held that the architect was responsible and should pay for a defect which was admitted by the contractors to be their fault.

Those who are not properly informed as to the duties of an architect assume that he should be held responsible for any and every defect in a building, notwithstanding that he may have little or no say in the choice of the contractor. It is utterly impossible for an architect to obtain perfect work in these days of keen competition, more especially when the proprietors refuse to pay for perfect or even passable work. In this instance the class of work was an inferior grade and the defect was a matter of no moment. An architect should be held responsible for defective work when it is self evident that he could not prevent same except at such an undue loss of time on his part as would make it advisable for him to pay the proprietor to take his work elsewhere. A commission of 5% on the total cost of the work will not permit of an architect remaining on a building and acting the part of foreman for all the trades thereon employed.

The question now arises as to whether this architect should not claim and be awarded damages against his lawyer because he had not brought out sufficient evidence at the trial to secure for his client a complete victory.

The cases are analagous and if such a case were tried before the same judge, in the same court under similar circumstances, surely he would have to give similar judgment.

It would be interesting to know if an architect had ever before been held responsible or made to pay for a defect in a building after the contractors had been paid in full and the building taken off his hands by the owner.

The Egyptian decorator was a priest, or a priest's servant, and his business became hereditary. The Indian decorator was a servant of the family, and his situation also frequently descended to his son. In China and Japan the decorators were in the earlier times priests working from a religious motive. With the Greeks, too, religion fostered the arts: so in the mediæval ages. It was not till the Renaissance, when the invention of printing led to the spread of knowledge, that individual excellences brought the individual out from obscurity, and we have styles of decoration as diversified as the people who produced them. In Japan the decorator originally worked with the utmost patience and loving care to illustrate his religion; thus decoration came to be practiced by princes and persons belonging to great families. At last it came down to the art workman, who, in Japan, with no competition, no machinery and but few wants, made everything he produced instinct with beauty.—Work.

ON THE BEARING AND RESISTING STRENGTH OF STRUCTURES AND THAT OF THEIR COMPONENT PARTS AND MATERIALS.*

By Chas Baillairge.

Many failures have, of late years, occurred of various buildings or of portions thereof, due to faulty, hasty or unmatured construction, and hardly a day passes but what the newspapers chronicle some catastrophe, some collapse of a building just finished, or even before it is finished, as evidently incapable of supporting its own weight, let alone that of the living or dead weight, or both, which it should have been made strong enough to bear. Such failures have occurred, in Canadian as well as in United States and European cities, and in most cases with the loss of one or more lives.

Much more attention should also be bestowed on the erection of temporary stages or platforms in cases of reviews, races, athletic and other performances; but with this, which is of secondary importance, and where sufficient solidity of construction can be arrived at without subjecting the structure to abstruse calculations, or to anything more than giving it due consideration, we do not intend to deal.

The engineering of architecture must be more closely attended to by architects, as the engineer will take the matter out of the architect's hands; and that would be a slur to the profession which should and must be avoided. Not that engineering structures in this respect are always scathless, for there are also many cases on record of the failure of a bridge, a subaqueous tunnel or other such structure, but these are comparatively few and far between, while architectural mishaps are of far more frequent occurrence.

Our friend Mortimer, publisher of the Canadian Architect and Builder, rehearses the fact at page 112 of his "Hand-Book" that the ultimate strength of a wall or pier of good hard burnt bricks in good lime mortar, as given by Kidder, of Boston, is 1,500 lbs. to the square inch, say 216,000 lbs. or 108 tons to the square foot—while the use of Portland cement with the best hard burned bricks, increases the resistance to 2,500 lbs. to the inch, or 180 tons to the foot—though previous competent authorities have given results from 30 to 50 per cent. less than these. Assuming therefore the known weights of mortar and cement brickwork per cubic foot, it would require a wall or pier to be from 1,600 to 2,700 feet high to crush the bottom bricks; and since such extreme cases have not and can never occur in practice, and that walls do fall notwithstanding, which do not even reach to one-tenth of the height, it is evident that not only must the mere crushing elements be made factors of, but other important data of length, breadth, height and thickness, and these are the considerations which apparently, from seldom or ever entering a builder's mind or that of a would-be architect, lead to the repeated accidents and fatalities of every day occurrence in some part or other of the civilized world.

Now, this knowledge is at hand and to be found at page 109 of the "Canadian Contractor's Hand-Book," which gives the proper thickness of brick walls for dwelling houses up to 100 ft. in height; though, of course, there are other considerations to be dealt with, such as the supporting, staying or stiffening ministry of the successive tiers of joists or beams, whether of wood or iron, which enter into the structural arrangements of the building, important among which is the necessity that beams which would be otherwise of too lengthy a span and therefore liable to dangerous oscillation and destructive leverage on the walls, be supported at intermediate points by other walls and piers restorative of the necessary stiffness to insure stability.

When, however, a structure becomes very high and heavy, as with the present tall buildings like the Philadelphia city hall, the New York World (22 story) printing establishment, the American Surety building (307 ft. high above the sidewalk and may be 20 to 30 ft. below that level), the Manhatten and others in New York and Chicago, and a beginning in that way in Montreal and other cities—it then behoves the architect charged with designing the structure to take crushing weights into consideration, and especially when the buildings are designed to be fire proof; and that, to that end, the floors are beamed with iron joists, brick or terra cotta archings or vaultings between, and concrete haunch or spandril filling with tile or cement floors to boot; and which, including weight of superincumbent partition walls and columns of the floor or story next above or resting on and supported by the columns next below, and with 90 lbs live and dead weight additional for persons, furniture and fittings of all kinds, may be taken at 300 lbs. per foot sup. of floor space.

To this end, I have thought on retiring from the presidency of the Association of Architects of the Province of Quebec, it might not be amiss for me to tabulate, as I have done herein-below; and for the ordinary spans or intercommunications of 10x10 ft. centres, 10x12 ft. centres, and 20x20 ft. centres, or for floor spaces of 100, 200 and 400 ft. area respectively, and for each and every successive story of a building as I have done, the sectional area in square inches of steel built columns to support the weights, the thickness of their component plates, the weights in tons to be supported and in the last three vertical columns of the table the corresponding prices at a uniform rate of 5 cents to the pound—while if 6, 7 or 8 or ten cents to the pound or even more or less are to be allowed, as fluctuating with the market value of the metal to be put in place at any time, then can the whole, the total cost be added to or deducted from by a known percentage of 20 for one cent additional, 40% for 2 cents, 50% for 2½, 60% for 3, and 100% for 5, and so on; for in addition to the possible price of iron or steel being greater or less, there is also to be estimated the average cost of first raising the weights to the average height of the structure, which, should the stories average 12 ft. in height, would be 120 ft. for a 20 story building, 60 ft. for a 10 story building, and so on of other average heights.

To simplify and speed me in the computation of the table, I have assumed one unique type of section or build of the supporting column of 12"x12" from out to out with central web, the whole put together with valley, or angle or flange iron, riveted together as shown in diagram in the margin or herein below; but, as with this form and size of section, the plates for a 20 story structure reach to two inches in thickness or more, it is evident how by increasing the size of column to two feet square instead of one, or four feet bearing area (2' x 2') the plates would thus be reduced to ½ an inch in thickness instead of 2" or to a thickness of one inch, by doubling the bearing area of column or making it 1.'42 x 1.'42=2.0164 square feet, or simply 1.'4 x 1.'4=1.96 square feet, which is near enough for all practical purposes, when the factor of safety, as in this case, is already on the safe side.

Or again, instead of the posts or columns being exactly square, it might suit better to double the dimension one way, leaving the other as it is: for instance, 1 ft. x 2 ft., or 12 in. x 24 in. for inch plates instead of 2 in., or for ½ in. plates 1 ft. 6 in. (18 inches) x 2 ft. 8 in. (32 inches,) or any other form of section to suit, as round or oval, etc.

The tabular statement does not give weight of column, but taking item No. 1, the sectional area in square inches is given as 10 square inches and the thickness of plates at 0.1 in. (one-tenth of an inch). Now, how this is arrived at will be immediately seen on reference to the diagram, for, as evident, there are four plates each 12 in. wide, one web plate 6 inches, and 8 valleys of 3 in. x 3 in. or 6 in. in developed breadth, together 102 or say 100 inches in total horizontal girth. Now 100 in. x 0.1 in. = 10 in. or 5/6 of a square foot. of inch thick iron per lineal foot of column. Again, wrought iron being 480 lbs. to the cubic foot, gives 40 lbs. to the square foot of inch thick space, or for 5/6 of a square foot 33⅓ lbs. per lineal foot of column, and this into 14, the assumed height or length of column, gives 467 lbs., or with rivets say 480 lbs., which at 5 cents the pound, give the figures $24.00 in the corresponding column opposite item No. 1 of table.

Or it may be plainer or easier to say that 102 inches total horizontal girth of plate and valley iron in the section, gives (dividing by 12) 8½ superficial ft. of iron or steel plate 1/10 in. thick, and as iron 0.1 in. thick = 4 lbs., therefore does the 8½ ft. give as before 34 lbs., or neglecting the 2 odd inches (more than allowed for in not deducting the twice computed angles of the valley irons) 33⅓ pounds.

Now this unit of weight and cost of column opposite item 1 for a 20 ft. x 20 ft. space or 400 ft. area, which at 300 lbs. a foot of floor surface gives the 60 tons in the sixth column, must of course be half of itself when the supported area is only 20 ft. x 10 ft., and ½ of this last or ¼ of itself, where the supported area is only 10x10 or 100 sup. feet, and so is also the thickness of iron reduced to 0.05 in. and to 0.025 in. respectively, and the corresponding prices in the two last columns to $12.00 and $6.00 respectively.

Again, as herein before stated, as to how to increase the area of bearing surface of column to reduce thickness of plates to inch or half inch—so in a converse manner may the 12 in. x 12 in. columns of the upper floors be reduced to half their size, or to 6 in. x 6 in., instead of 0.1 in., or to 6 in. x 12 in., and the plates increased to 0.1 in. for column 7 of table instead of 0.05 in., and to 0.05 in. instead of 0.025 in. for column 10 of table.

It will likely be evident, or at any rate there can be no harm in remarking, that in computing by this table for a building of any number of stories the process must be from above downwards, and can not be from below upwards, except in the case the table is made to suit, to wit: A building 20 stories high, for the upper story supporting only the roof will remain invariable, and if the total height of structure were, for instance, only nine stories, then would item No. 9 represent the data for the first tier or story above street level with Nos. 10 and 11 for basement and sub-basement.

I herewith also give a table for a corresponding building with brick piers instead of iron, where the cost of brick work in cement at as high as $20 00 per mil (taking its crushing strength at 180 tons to the square foot, with a factor of safety of 6, or assuming the square foot of pier as capable only of supporting 30 tons) just comes to half the corresponding prices of iron or steel at 5 cents a pound, or would be a quarter of the cost thereof if at 10 cents the pound. Such piers as those given of a sectional area of only one square foot opposite item No. 1 of table, column No. 7, and of 1½ square foot on the same line of column No. 10 (the latter especially not being possible in practice), it would of course be necessary with such weights to bear, to have made of steel or iron or corresponding strength, or as indicated at columns 7 and 10 of table No. 1—and it might moreover be prudent to do the same with the smaller or more delicate piers of items Nos. 2 and 3, or if not, to continue up these piers of undiminished size from items Nos. 3 or 4, or even 5 according to circumstances—as, though theoretically capable of bearing the weight, such light brick structures would be dangerous of overthrowal by a comparatively slight side thrust.

On the other hand, as seen by the table, the corresponding sizes for the lower floors or stories become so great, that they would be altogether inadmissible on account of the space thereby lost to useful purposes; and the object of this second table is rather to show the inadmissibility altogether of brick work in the premises, as even though the cost of structure might be thereby reduced, it would be false economy to lose so much useful space, to say nothing of the very awkward appearance of such a structure; and again, with most companies requiring such structures and with no want of funds to provide them, cost is generally a secondary consideration—each insurance or other company or trust or syndicate striving to outvie its neighbors in magnificence and cost of structure. And this emulation exists even among individuals, as I am proof to, when on one of my visits to New York on inspection of an ordinary 25 ft. brown stone front dwelling house on Fourth avenue, which with its marble stairs and skirtings, etc., had cost its proprietor $100,000, the proprietor of the neighboring lot with an old-fashioned brick house thereon, seriously asked his architect if he could not build him one which would cost more money, to which, of course, the architect immediately assented. We don't have such chances as that in poor old Quebec, where we are on the contrary always met with the demand to do things for half their value.

The construction of these high buildings is rendered possible only by the use of steel frame or skeleton work. The older type of buildings, whether of stone, brick or iron, depended for its strength upon its walls. The modern tall office building has a steel frame. This carries merely the whole weight, and the walls, solid and massive as they may appear, do not support the structure, but simply fill the interstices. It is startling to think of the entire superstructure of a 20 story building resting on some 30 or 40 columns; yet, without this modern development, without the use of steel, the walls would have to be so thick at the lower stories that there would be no room left for offices. The steel represents the osseous structure of the animal, while the enveloping masonry surrounding the same exemplifies the flesh or meat, which saves the skeleton from the extremes of temperature and thus from the exertion of contractive and expansive forces which might otherwise jeopardize the structure.

It becomes important also, if not imperative, as a factor in the computation of the necessary bearing areas of the foundations supporting structures of the kind, to consider as data for comparison, what weights are permissible to the square foot of underlying piles or piers, or of the natural soil when of a nature to subserve the purpose—some of the columns bearing weights varying between 600 and 1,300 tons in the American Surety building already alluded to.

The inequality of the weights borne by a square foot of the foundations of the buildings mentioned in table III may appear striking at first sight, but they are due to the weights being distributed over greater or lesser areas of the supporting soil. For instance, in table I, item No. 21, we have 1,260 tons supported by a steel column a foot square, while in the American Surety building some of the columns are loaded to 1,280 tons, but these

*Paper read before the Province of Quebec Association of Architects at their annual meeting at Quebec, October 2nd, 1895.

are about 2 feet square, or of an area of 4 feet, which at once reduces the pressure per super foot to 320 tons; and if the foundation piers bearing these and transmitting their weight to the solid rock below were only 10 feet square, or 100 feet area, the weight per foot reduces to a little less than 13 tons; while if the pier be made 14 feet square, its area is doubled and the 13 tons reduced to 6½ or 6 as set forth in table. As stated last year by the writer in his paper on the foundations of heavy structures, the question is not so much the number of tons which 1 foot of bearing surface is loaded with, as that (not to prevent settlement which is inevitable, but to render it equal throughout) the bearing surfaces of foundation be equally loaded—the whole front of the new Joliette church having to be rebuilt at a cost of some $10,000 because, while the side walls bear with only 2 tons weight or pressure on their footings, the tower and front wall bearing on their footings with a pressure of 4 tons or double the weight. The tower, when I saw it three years ago, had torn itself and the portal away from the aisle walls and sank to a depth of more than 11 inches below the latter, completely dislocating and destroying this portion of the structure and requiring its entire demolition and reconstruction.

One would think at first sight—that is, the popular idea may be and is—that a solid structure or one of solid masonry like the pyramids, is that which with the same height and weight of material, bears heaviest on its foundations, but such is by no means the case, the greatest pressure being generally borne by the piers of a domed church or other structure, each pier being loaded, in addition to its own weight and portion of dome bearing directly on it, with one quarter of such portions of the vaulted or arched structures as correspond to the archways or openings of the aisle and transept, and which, as in the case of St. Peters of Rome, must be close upon 35 tons to every square foot of the supporting pier.

Nor is there anything extraordinary even in this figure, as I believe some of the so-called chapter houses of churches in England support weights even in excess of this, where one-half the weight of the domed or stone groined vaulted ceiling is borne by a single marble column of only a few inches in diameter at the centre of the structure. Another example of heavy weights borne by a small base is where a 100 ton gun, for instance, or ponderous piece of machinery supported by the jib or boom of a derrick, is thus transferred to and supported by the derrick mast or upright post, which, if say of a 14 inches square piece of timber, giving a sectional area of only 2 feet or less, loads the bearer with a weight of 50 tons, together with the additional weight of the derrick itself, representative also the derrick post or mast of a column in any building and the boom or jib with its suspended weight, of the 100, 200 or 400 ft. area of supported flooring with column at 10'-10' centre, 10'-20' or 20'-20' distance apart, or (at 300 lbs. the ft.), 15 30, and 60 tons respectively.

Now, even 60 tons, or 160 to a square foot of a solid stone pier, not monolithic, but made up of monolithic or large and closely fitting cut stones, is in no way excessive, since good cement brick work will bear 180 tons, while good ordinary cement stone masonry will bear twice that weight or 360 tons, and up to twice that figure or even more; for the experiments made on a brick pier, for instance, are so made on one of only a foot square, and those on piers of masonry have also been made on comparatively small based areas, where there was no lateral support or resistance round about to prevent the giving away by lateral failure.

Again, the strength of piers of stone masonry may be made to approximate almost indefinitely to that of the stone itself, as given in the ensuing table IV, where crushing powers are recorded of as much as 1,200 tons and over to the square foot, or rather equivalent thereto, and which would be much greater if it were possible, which it practically is not, to test a foot of stone in the same manner instead of only a small cube of an inch or an inch and a half square and then reduced to inch; for the small cube, as would also be the case with a piece of a larger one, must necessarily fail first at the angles or corners and along the edges, while if the same weight or pressure were applied to an equal area at the centre of a 12 inch stone or more, it is evident it would produce no effect, the tendency to crush and crack being counteracted by the lateral support given to the central portion by the strength and resistance of the outlying margin of the material experimented on.

And not only would the crushing weight of masonry approximate to that of the solid stone, as determined by experiments upon the tiny cubes thus treated, but there can be no doubt of it, go far beyond such data and indefinitely so, for even if the nucleus of the earth be fluid, and the crust only 40 miles in thickness as geologists pretend, and if the crust be stone and even if no heavier than granite, then would we have on each square foot of the inner rim or area of base thereof, more than 200,000 cubic feet of stone, and at 160 lbs. to the foot, a crushing pressure of 16,000 tons, but which, were it ten times greater, a hundred or a thousand times, could never crush the stone, supported on all sides as is every foot of the crust or solid component masonry thereof by the equally resisting power of every other foot bemming it in on all sides and preventing the possibility of its ceding or giving away to any other force than the disrupting seismic action of the interior.

I must, gentlemen, insist again, as I did in my last year's paper on "Foundations in Deep and Unreliable Soils," on the necessity of a consideration, not only of absolute, but of comparative stresses to secure uniformity or prevent inequality of settlement—that being the all-important desideratum.

The very term "the engineering portion of architecture," or rather the necessity for such a term, is a slur on the profession, an insult so to say to any architect who pretends he knows his business; for if we are to call in the superior scientific acquisitions of the engineer in dealing with the foundations, then, a fortiori, shall we have to do so in dealing with the stresses, much more difficult of calculation, of a domed structure, for instance; and surely it never shall be said that the architect has come down from the high pedestal on which, long before the days of engineering science, stood and stand to this day the Bramantes and the Michael Angelos, the Perraults and the Mansards, the Jones (Inigo) and the Wrens. Well may we hide our heads if ever that should come to pass, for, without the aid of the engineer, we architects can do as they do, and thus make themselves appear more scientific than they really are. Can *we* not also call in the aid of mathematics, and direct a professor or expert at that science to calculate a stress of any kind, whether of direct weight, lateral pressure, or resistance to overthrowal by a cyclonic wind or pressure.

If the profession would have that standing which it had of yore and still lays claim to in other countries, I must tell you, and I do so squarely—we must hear of no more such failures as those at Nicolet, St. Bastile, Joliet, Cornwall and elsewhere. Nor should there be any more roof failures, whether from rain saturated snow or due to faulty construction. Montreal must not in respect to falling buildings emulate New York, where such accidents are the order of the day, which are to the disgrace of the profession.

But though or while giving you a table for calculating the component weights and strengths and costs of a building up to 20 storeys in height, I hope none of you will ever be called on to design such an ungainly, unaesthetic piece of construction, and at any rate that you will set your face against anything of the kind elsewhere than in but a purely manufacturing or suburban district, and not where its presence would mar the landscape and architectural effect of surrounding common sense structures; and I here transcribe a most pertinent article from the "London Surveyor." It reads as follows:

"A *proposal* of a monstrous "sky-scraper" apartment house recently erected at Washington, the American Architectural Record has a deservedly severe article on "Architectural Aberrations," and puts forward the plea that city authorities should be allowed to veto plans for new buildings, not only if they sin against sanitary laws, but if they outrage the canons of art. As it pertinently remarks, "There is a patent absurdity in taking thought and spending vast sums of money for the purpose of making a harmonious city, and then permitting any promiscuous private person who can get possession of a piece of ground, and raise money enough, to put a building on it, to nullify all your dispositions and vulgarise your town." There is much in the protest, and though we do not suffer so badly as our cousins do from the *piled-up monuments of bad taste and cupidity*, still even London suffers from the tall-house mania, not to mention other hideous forms of architectural aberrations. Edinburgh, too, will note the timely protest with interest. But the task of acting as censor would be full of difficulties where mutable taste rather than positive science would have to be the guide."

To this I would add that there should be no foolish rivalry in such matters, as it is as easy for one architect to outdo another in height as for a naval architect to beat the record in point of length and strength, or for an artillerist to design a target that will resist a shot, a shot to pierce it, another target to resist the latter and again another shot to hole it, and so on, without end; but though there may be a reason for this when a nation wishes to retain its prestige over its neighbor; and though engineers are forced into long and still longer spans for bridges due to the widths and depths of rivers to be traversed and to conditions imposed by the authorities—as in the 1,700 feet twin spans over the Firth of Forth in Scotland, the Brooklyn suspension bridge and now the 3,200 feet span structure about to be thrown over the Hudson between New York and Jersey City—no similar necessity exists for structures of the Eiffel tower type, which all Paris is clamorous to have demolished, though it certainly is not an outrage to artistic taste and merit in any way approaching the super-

Type of steel-built column on which calculations of stresses, weights and prices are based, for computation of data in Table I.

Scale, ¼ inch to one inch.

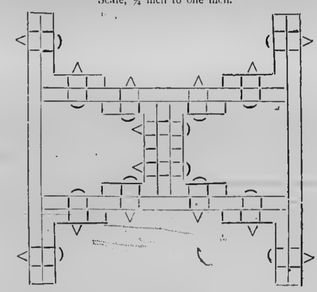


TABLE I.

Table of steel thicknesses and sectional areas, box built columns to support fire proof or iron, brick and concrete floorings in buildings from 1 to 20 stories high. Weight per sup. or square foot of roofing and flooring, partition walls, etc., 300 lbs., including 90 lbs. live load. Factor of safety = 5 or 1/5 of crushing load.

posed box-like piles which are now in a fair way to disgrace our neighbors in the eyes of European nations.

Gentlemen, let us also be severe in architecture, to the extent at least of not allowing it to assume, as it is bidding fair to do in Ottawa, the phase of what may be called "bed post architecture," and in truth, though there are hundreds of otherwise very pretty villas and cottages in the new Capital, quite a number of their verandas and entrance porches are rendered hurtful to the eye of good taste, by being supported on bed posts, for they certainly cannot be called columns. And to cap the climax, in some of the twin dwelling houses or where there are two doors side by side, with a veranda or portico in common, the separation between the doors is for all you can imagine, of the exact shape of a partition between two horse stalls.

TABLE II.

Comparative table of sizes or sectional areas of brick piers to support fire proof or iron, brick and concrete floorings in buildings from 1 to 20 stories high. Weight per sup. ft. of roofing, flooring, partition walls, etc., 300 lbs., including 90 lbs. live load.

No. of Item for reference.	No. of stories counting up-wards.	No. of stories counting down-wards.	Piers at 20' - 20' centres. Area supported 400 sq. ft. Area of pier in sq. ft., ins.	Size of pier square.	Weight supported in tons.	Piers at 20' - 10' centres. Area supported 200 sq. ft. Area of pier in sq. ft., ins.	Size of pier square.	Weight supported in tons. TABLE III.

WEIGHTS PER SQUARE FOOT OR SUPERFICIAL FOOT BORNE BY PIERS AND FOUNDATIONS OF CERTAIN BUILDINGS, BRIDGES AND OTHER STRUCTURES.

Says Professor Butler, as given by Mortimer at page 104-5 of his "Hand-Book":

	Per sq. foot.
The load on the monolithic piers supporting the large churches in Europe does not exceed (early builders using much more massive masonry, proportionally to the load to be carried, than at present)	30 tons.
The Toff bridge in France	21 "
Former bridge at same place said to have failed at	64 "
Rennie subjected good 4 ft. rubble piers to	22 "
Granite piers Saltash bridge, England	9 "
Brooklyn bridge piers	29 "
St. Louis bridge piers before completion	38 "
The same after completion	19 "
Niagara suspension bridge limestone towers failed under	36 "
Maximum pressure on rubble masonry and cement mortar of some of the large masonry dams	14 "
Proposed Quaker bridge dam—270 ft. high	17 "
The following are from the writer and others:	
At centre of the Cheops pyramid say	40 "
Piers of the dome at St. Peters (the great thickness of these piers, say 20 to 30, renders the confined centre as resisting, so to say, as solid rock), say about	35 "
Weight on foot side walls Joliette church	2 "
Weight under tower (causing failure by sinking or settlement)	4 "
Strasbourg Cathedral tower, say	40 "
Washington monument, 555 feet high	45 "
Tower of Babel or of Belus, 650 ft. high, say	52 "
Central piers Britannia bridge	33 "
"Manhatten Life" building, 353 ft. high	15 "
The "Equitable" building and Union Trust, built with wide footings, load the foundations, it is said, only to	3 "
Proposed Hudson river bridge, 3,200 ft. span piers	26 "
The Stock Exchange, Chicago, is said to load the foundation soil at	4 "
Allowed by New York city regulations	15 "
Load per foot square of foundation brick piers of American Surety building, say	6 "
The author's design for the proposed London Eiffel tower (see fig. 5, page 18, of the 68 designs sent in, printed and published for "The Tower Company, Limited," by "Industries," 358 Strand, London, under title of "The Great Tower for London." Height of tower 1,600 ft., diameter at base 280 ft., total weight 14,303 tons, 20' wide offset balconies at every 200 ft. of total height, greatest weight on lower column at centre	117 "
Average weight on the 312 first tier columns	46 tons.
Total weight distributed by inverts or footings over the 61,600 ft. area, less than	¼ "
Weight at centre distributed by inverts or footings over the 100 ft. sup. of bearing to each colum at centre of tower	1⅜ "
Brunel (Paris) design for proposed London Eiffel tower, 500 ft. square, 2,296 ft. high, of granite, weight 196,902 tons, weight per foot square supported by bottom piers	160 "
Weight per square foot distributed over soil area of 250,000, say	4/5 "

TABLE IV.

CRUSHING TESTS OF BUILDING STONE.

For many years the resistance to crushing force shown by a building stone has been considered high evidence of its homogeneousness and durability.

The following table gives the resistance to crushing per square inch, shown by various stones, granites and marbles, and is compiled from General Q. A. Gillmore's report to the Chief of Engineers, United States Army; from Haswell's Engineer's Pocket Book; from "Stones for Building and Decoration," by Dr. Geo. P. Merrill, of the Department of Geology, Smithsonian Institution, and from tests made by Mr. Ira H. Woolson, C.E., at the request of the Professor of Geology of Columbia College School of Mines, on the Emery testing machine belonging to the college. Where tests have been made on a number of specimens, the highest result is given.

Paving brick should stand 10,000.00 to inch crushing force and absorb not over 2 to 3 per cent. of water.

CRUSHING WEIGHT PER SQUARE.

	Inches in Pounds.	Feet in Tons.
Aberdeen, Scotland, Granite (Haswell)	10,760	774.7
Albion, New York, Sandstone (Gillmore)	13,500	972.0

ILLUSTRATIONS.

A COUNTRY RAILWAY STATION.—F. S. BAKER, ARCHITECT.

PROPOSED HOUSE FOR MR. A. A. DIXON, TORONTO.—SIDDALL & BAKER, ARCHITECTS.

ST. MARY'S SCHOOL, HALIFAX, NOVA SCOTIA.—DAVID STERLING, ARCHITECT.

THE building is situated near to the Cathedral, and faces on Barrington street. It is constructed of pressed brick with granite facings.

COLLEGIATE INSTITUTE, SARNIA, ONT.,—S. H. TOWNSEND, ARCHITECT, TORONTO.

THIS building, erected in 1890, is constructed of plain brick with tile gables. It was built by day labor, a local builder, Mr. Proctor, acting as clerk of the works. The cost was about $25,000. The building is 80×95 feet in size, and in plan is acknowledged to be particularly well adapted to the requirements. In the basement are large play rooms to meet the needs of the students for recreation when the weather is unfavorable to outside sports. The top story of the building is occupied by an assembly hall, with pannelled walls and open timbered roof, and fitted up with dressing rooms and stage.

SIDE TALKS WITH THE BUILDER.

THERE are many builders who have a practical knowledge of brickwork and know how to construct an excellent piece of brickwork, writes R. N. Buell in The Brickbuilder, but are careless or ignorant regarding that most important part of every building, and that upon which their structure depends most entirely. A poor stone wall has been the cause of ruining many a noble and otherwise perfect edifice. Let me give my brother masons a few pointers on laying stone—not that I shall attempt in these columns to give an exhaustive treatise on the subject, but simply to place before him a few simple rules, which may possibly be the means of saving him many dollars.

Of whatever quality the stone may be of which a wall is to be built, it should consist as much of stone and as little of mortar as possible. If it be inferior in durability and power in resisting the action of the atmosphere, etc., to the mortar, besides the certain fact that the mortar will yield until it has set hard, and so far act injuriously, no ulterior good is gained; and if the stone be the more durable material, the more of it that enters into the wall the better. Indeed, in rough walling, if the stones be laid so that the most prominent angles on their faces come into actual contact, the interstices being occupied by mortar, it will be better than if a thick, yielding mass were allowed to remain between them. Absolute contact, however, should not be permitted any more than in brickwork, lest the shrinkage of the mortar in drying leave the stones to such unequal bearing as the prominent parts alone would afford.

Stone being generally of a less absorbent nature than brick, it is not a matter of so much importance that it be wetted before setting. Nevertheless, adhesion on the part of the mortar is more certain and more complete if the stones be worked in, at least, a damp state.

Bond is not of less importance in stone walling than in bricklaying. Instead of carefully making the joints recur one over the other, in alternate courses, as with bricks and gauged stones, the joints should as carefully be made to lock so as to give the strength of two or three courses or layers between a joint in one course, and one that may occur vertically over it in another. In bonding through a wall or transversely, it is much better that many stones should reach two-thirds across alternately from the opposite side than that there should be a few through stones, or stones extending the whole thickness of the wall. Indeed, one of the many faults of stone masons is that of making a wall consist of two scales or thin sides with through walls now and then laid across to bind them together, the core being made of mortar and small rubble merely. This is a mode of structure that should be carefully guarded against. There is no better test of a workman's tact and judgment in rubble walling than the building of a dry wall, or a wall without mortar, affords.

Walls are frequently built with mortar that without it would have fallen down under their own weight in a height of 6 feet in consequence of their defective construction, thus rendering it evident that they are only held together by the tenacity of the mortar, which is very seldom an equivalent for a proper bond of stone. Masons are very apt to set thin, broad stones on their narrow edges to show a good face, by which the wall is injured in two ways. It tends to the formation of a mere case on the surface of a wall, and it for the most part exposes the bed of the stone to the atmosphere, as a stone is more likely to be broad in the direction of its bed than across it.

ST. JOHN, N. B., EXHIBITION.

THE recent Exhibition at St. John, N. B., reflected credit upon the Maritime Provinces, and attracted not only local exhibitors, but manufacturing companies in the upper provinces. The attendance was worthy of the interesting character of the exhibition.

The Toronto Radiator Manufacturing Company, and the Toronto Steel Clad Bath Company had interesting exhibits of their goods at this Exhibition. The exhibits were in charge of their St. John agents.

Amongst other exhibits of materials relating to architecture and building was a display of memorial art glass by Mr. Frank Reardon, of Halifax, N. S., and an exhibit by the Mosley Folding Bath Tub and Water Heating Company, of Chicago. Mr. Frank Welliday, of St. John, N. B., is the Company's Canadian agent.

PRESTIGE.

IN an interesting paper on the subject in Fame, Mr. Milton J. Platt says:

"Here is a simple question. Do advertisers for high class patronage pay sufficient attention to the prestige of the mediums they use?

"Prestige is not a mushroom growth, it cannot be bought; it must be earned. Space in the medium possessing it is worth to the seeker for a high grade of patrons an incalculably greater sum than space in the medium without it. This is also true, even though the latter's circulation equalled that of the former, and even though it were claimed for it, that 'it goes to the same class of readers.'

"Webster tells us that prestige at one time meant 'delusion; trick; illusion.' Those definitions are no longer applicable to the word itself, but they very nicely express some of the qualities attaching to more than one publication which claim kinship with those commonly known to be above suspicion. The present use of the word implies weight of influence drawn from past success; expectation of future achievements founded upon those already accomplished. This is the prestige the wise advertiser will look for, and the names of the magazines or other publications possessing it will at once occur to him."

THE WIDOW'S TENTH.

A CASE of unusual character came before Judge Ferguson at Osgoode Hall, Toronto, the other day, in the way of appeal from the finding of the master. Mrs. Nightingale, of North Toronto, filed a claim against the executors of her husband's estate, under an agreement which had been made between her husband and herself when he commenced business as a brick maker, to the effect that she should receive one brick in every ten manufactured. The judge decided in her favor.

The case of Mr. Neelon, contractor, for the Toronto Court House, against the city of Toronto, has reached the Supreme Court at Ottawa, where it is now being argued.

Supplementary letters patent have been issued to the Hamilton Bridge Works Company authorizing an increase of the capital from $10,000 to $150,000.

Complaint is made that a contract for $1,099 worth of sewer pipe for Victoria, B. C., was made by the sewer committee without the consent of the city council, or advertising for tenders. The rule is that no liability exceeding $50 can be incurred except by the council as a whole.

Joseph Lamarche, contractor, is suing the city of Montreal for $7,500 damages for injuries sustained by him in May last, when he fell and broke his leg. He claims heavy damages on the ground that it interfered very much with his business and that he suffered for the above amount.

USEFUL HINTS.

The French and English papers, which are now used, come without friezes, which is a distinct gain in the matter of height, while it possibly detracts from the breadth of a room.

The correct principle to observe in hot air heating is to supply a large volume of warm air, at a lower temperature flowing through the registers. Don't use a small furnace heated to a red hot heat, with small cold air supply, and a high temperature at the registers; the latter plan is one that causes trouble, and brings condemnation to furnace heating.

AUTOMATIC COPYING OF LARGE DIAGRAMS.—To secure exact copies, by the action of light, of large-sized illustrations and diagrams the prepared paper must be in immediate contact with the glass negative or the drawing. A certain pressure has, therefore, to be exerted, which is apt to break the glass. Mr. H. Sack, of Dusseldorf, spreads the paper on a rubber plate, and creates a partial vacuum between the rubber and the glass. The frame is made of pitch-pine: the apparatus resembles a light table running on four rollers. The vacuum can easily be produced by means of a hand-pump, a pipe for establishing connection being fixed to the table.

TRACING DRAWINGS.—A correspondent writing to an English architectural journal relative to the method of tracing drawings presents the following suggestions: Prepare the tracing cloth or paper by first rubbing on it some finely powdered French chalk, and then for doing the tracing use Indian or Chinese ink, in which a small quantity of prepared ox-gall has been rubbed up in ink. The tracing may be done by means of a good drawing pen.

A fire-proof building is being erected on the corner of Craig and St. Lambert sts., Montreal, for the main office of the Street Railway Company. About 500 tons of iron girders will be used in it. The floors will be of terra cotta. It is so constructed that none of the weight of the upper storeys rests on the walls.

TO ARCHITECTS, BUILDERS AND CONTRACTORS

We are prepared to furnish from our quarries in New Brunswick

BROWN AND OLIVE
FREE STONE

of the finest quality and of any dimension.

Samples forwarded free and quotations given on receipt of inquiry . . . . . Correspondence solicited.

WM. HOOD & SON 10 Richmond Sq. MONTREAL.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2⅞ × 3	2⅝	131,000	15,188	
C	2 1/16 × 3	2⅝	130,000	14,751	
D	3 × 3	2⅝	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have a large quantity of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

TO the writer, who had occasion recently to visit the Toronto custom house, it seemed incongruous that side by side with iron doors and shutters, and other safeguards against fire, should be seen in active operation that relic of a past era, the coal oil lamp.

JUDGE MCDOUGALL, of Toronto, has decided, in a county court suit for $147 for 25 toise of stone, that stones are part of the land upon which they are found and cannot be removed by the tenant. Few land owners, however, will be found to object to having the loose stones removed from their property. Quarrying the stone is another matter.

WE referred in a recent issue to the quality of Canadian cement. Since then we have heard of tests applied in Montreal to a cement made at Vancouver, which it is said show it to be far superior to the English article, the difference in breaking strain being as 150 to 90 in its favor. Mr. Warsap, the manager, has just returned from a two months' visit to England, and the manufacture of the cement is to be carried on with renewed vigour.

APROPOS of the reference in these columns last month to the effect of ivy planting upon architecture, the statement has since been made in the daily press that it is the intention of the Ontario government to plant "creepers" round the Parliament buildings. The proposal has our hearty approval. Something in the nature of a disguise to the outside of these buildings has long been recognized by persons of cultivated taste, to be a necessity, and the announcement that the want is to be provided for will be hailed with pleasure.

SOMETIMES when condemning the extravagance of our governors in expending money on needless public works, we have consoled ourselves with the reflection that after all they paid for themselves. Some figures recently presented to the Montreal city council dispel that idea. They show that while the city debt had, during the past six years, increased 120 per cent., with a corresponding increase in interest charges, the revenue had increased less than 50 per cent. It does not pay a community to have its money squandered upon public works.

THE city of San Francisco has recently passed an ordinance limiting the height to which new buildings may be erected to 125 feet on streets over 100 feet wide, and 100 feet on streets of less width. The California Architect, in discussing the ordinance, prints some of the arguments for and against high buildings, and concludes by saying: "It seems to us that all these conflicting interests would be harmonized by the adoption of the rule that no part of a building on one side of a street should extend beyond a line drawn from the foot of the building on the opposite side of the street, at an angle of forty-five drgrees; this gives the public and the adjacent owners of property their share of sunlight and air—and at the same time allows a man to build as high as he likes on the rear portion of his lot, as long as he does not obtrude upon that forty-five degree line."

ST. LOUIS, like Toronto, is erecting a city hall, but it is hoped that the experience of the latter will not be that of the former. A committee of investigation has discovered numerous defects and weaknesses in the partially completed St. Louis building, which has already cost the city over $2,000,000, and which will have to be largely reconstructed. Toronto's complaint is not so much structural as financial.

MR. JAS. J. CURRIE, of Abbotsford, B. C., has sent a long communication to the New Westminster Board of Trade, in which he elaborates a plan for the construction of dwellings for the working classes in London, England, the material to be sawdust and other refuse reduced to pulp and moulded into planks. Artificial lumber of this kind is no new thing, but we question whether the freight from British Columbia on either the sawdust or lumber would not be too high to make it pay.

MR. JOHN J. FOY, of St. Louis, presented to the National Association of Master Plumbers of the United States recently, a lengthy paper, the title of which was, "Should Master Plumbers Handle Tools?" No general answer, affirmative or negative, can be given to this question. If the building business is active in the locality in which the plumber resides, it will probably be more profitable to him to pay journeymen to handle the tools while he devotes his time to securing contracts. If on the other hand, there are few contracts to be got, as has been the case of late in most of the cities and towns of Canada, the master plumber should not allow false notions of dignity to prevent him from taking hold of the tools and doing as much as possible of the actual work himself, thereby adding to his profits the money which under different conditions would be paid out in wages.

WE have recently received a communication from the Secretary of the Institute of Clay Workers, 222 Strand, London, asking our assistance towards obtaining specimens of Canadian manufactured bricks for the Institute's exhibition of manufactures of clay materials. The Secretary of the Institute adds that he would be pleased to see any of the readers of this journal who may at any time visit London, and to show them what is being done in England in the line of brick manufacturing. We trust that some of our manufacturers, in response to this invitation, will send to the Institute specimens of their products. In the manufacture of plain and pressed brick, terra cotta, and other clay materials, Canada has made wonderful strides during the past ten years, and we have little doubt that our productions in this line will compare favorably with those of other countries.

A GUILD of Sculpture has been incorporated in Ontario, to promote and cultivate the study and taste for that art, and for special training in designing, modeling, carving and working in metals. It is the intention to hold exhibitions and offer prizes for statuary, and to promote the establishment of a gallery. Ticket holders will receive statuettes or busts in terra cotta, and have a chance in the drawing of prizes. The president is Mr. L. R. O'Brien, R.C.A., the well known artist, and the Director of Arts, Mr. Hamilton MacCarthy, R. C. A., the equally well known sculptor. Mr. Emerson Coatsworth, M.P., is treasurer, and Mr. James Van Sommer secretary. The studios and office are at 28 Toronto street, Toronto. Officered by such men, and with a promising field, such a guild should, and no doubt will, be a success in promoting a love for this splendid branch of fine art.

A CANADIAN visitor to New York recently was impressed with the difference in methods of construction employed in that city compared with those pursued in Canada. In the construction of long stretches of wall in business buildings, the method usual in Canada of bonding each course of brick, is not followed; instead, it is the practice to lay a bonded course at regular distances, a few feet apart, and to fill in the space between these courses with brick bats, laid directly one upon another with a bedding of cement mortar between each course. It is claimed that this method of construction, which permits of the utilization of a large amount of what is here regarded as waste material, is not only cheaper but actually possesses some advantages over the Canadian method. One of these advantages is, that cracks due to settlement will affect only sections of the wall and not the entire structure, as is the case where bonded courses are laid throughout the building.

CANADIAN manufacturers who do an export business in iron materials are complaining of the treatment accorded to them by the Government in the matter of refund of duty. With the object of encouraging the use of Canadian iron, the tariff imposes a duty of 20 cents per cwt., or $4.48 per gross ton, on iron imported for manufacturing purposes from the United States, and in order that our manufacturers may not be placed at a disadvantage with American manufacturers as regards the ability to do foreign business, it provides for a refund of 99 per cent. of the duty paid by the Canadian manufacturer on American iron, when the article in which the iron is used is exported. These provisions are considered fair enough if properly carried out, but complaint is made that the Government has failed to provide any satisfactory means of arriving at the amount of refund, and some manufacturers at least, who are doing quite an extensive export business, have as yet not been able to secure a cent of refund. Manufacturers of iron goods which have to be subjected to steam pressure—as for example radiators—are obliged to use about 60 per cent. of American iron, in order to get the requisite amount of strength for their materials. It is apparent that it would be impossible for the customs inspectors to determine by examining the manufactured article just what percentage of Canadian and American iron it contained. The common sense way would seem to be to compel the manufacturer to submit to the Government proof of the amount of American iron which he is accustomed to use in the manufacture of a certain class of material, and upon this the rebate should be allowed in the case of material exported. Strange to say, however, the Government refuse to adopt this method, while neglecting to make provision of a more satisfactory character. The result is, that manufacturers are getting no rebate whatever, which means that American manufacturers are enjoying an advantage in foreign markets of something like $6.00 per ton. This condition of things should be remedied without delay.

It is alleged by manufacturers of certain lines of materials that there is need for a revision of the specifications under which tenders are received and contracts awarded for Government buildings. It is stated that under these specifications materials of certain manufacturers, who years ago were the only reliable makers of certain lines of goods, continue to be specified, thus shutting out the numerous other manufacturers who have come into the field in recent years. Some of these goods are of the most simple character, as for example supports for lines of steam piping, which can now be obtained from a score of different sources. It seems only right that all reliable Canadian manufacturers should be given an opportunity of submitting tenders for materials required for use in public works. The following order, recently issued by Secretary Carlisle, of the United States Treasury Department, recognizes the necessity for the change which our manufacturers desire to see introduced: "The supervising architect of the Treasury Department is hereby directed to eliminate from the specifications hereafter prepared in this office for the erection or repair of public buildings all requirements which demand from the successful bidder that he shall furnish certain specific materials or "equal thereto," and shall not use in connection therewith the name or designation of any individual, co-partnership, company or corporation. The said specifications must state in sufficiently descriptive terms the kind and quality of stone or brick desired, without reference to any particular quarry or manufacture; but these, and all other materials must be of the best quality for the purpose wanted, and subject to the approval of the supervising architect, without, however, naming any special make or brand of goods, or in any wise discriminating in favor of one specific kind of material as against similar material of equal quality. The supervising architect is further directed to settle definitely in his designs of public buildings the kind of material with which the walls are to be built, in order that controversies concerning the use of different materials may be avoided. This order shall take effect at once." Complaints are also heard of the difficulty experienced in securing copies of specifications, and answers to requests for information addressed to the Public Works Department at Ottawa. Mention is made of these matters in order that the complaints, if well founded, may receive attention at the proper hands.

CONCRETE AS A FIRE RESISTANT.

IN the last number of the ARCHITECT AND BUILDER we published a description of the method being adopted to render the new building in course of erection in Toronto for Mr. Robt. Simpson, as a departmental store, fireproof by means of concrete. The article has called forth a letter from "Architect," which appears elsewhere, in which he asserts very positively that concrete is not a fire resisting material, and that it is unsafe to use it where it will be subject to the action of great heat, which would have the effect of causing it to crack and disintegrate.

This is one of those cases where "doctors disagree," and when such is the case, who is to settle it? We have, since "Architect's" letter came into our hands, taken some pains to ascertain the views of different architects and experts on the subject, and find they are as widely apart as the poles. We shall be glad to have the matter discussed in our columns, for it is an important one, in view of the better class of buildings which are being constructed in our cities, and which their architects and owners are desirous of rendering as indestructible as possible.

The quality of concrete depends of course very much on the way it is prepared. If gravel containing limestone pebbles is used the application of heat will slack the lime contained in them and cause disintegration. If, however, slag or screenings are used (and slag, when obtainable, forms the matrix of the concrete used by the Simpson building contractors) disintegration would not occur to the same extent.

We have been shown the results of some very severe tests to which this concrete has been subjected, and assuming that they were fairly applied, they seem to indicate that it is what its supporters claim—absolutely fire resisting. The Board of Fire Underwriters of Alleghany County, Pennsylvania, which includes the city of Pittsburg, lay down the following specifications of a test, which will be required on all non-combustible floor construction before the same will be passed by the board:

"Enclose a space of eight feet square with a brick wall, having a protected steel beam in the center of same, thus having two half spans of floor arch enclosed; said beam must not rest on enclosure wall, but must be a 12-inch 32-pound beam with a span of 16 feet between supports.

Enclosure must be so arranged as to have a flue outlet and a door opening at the other side by which to feed fuel to fire bed.

Place furnace bed 4 feet below bottom of arch and maintain a mixed coke and wood fire at as high a degree of temperature as is possible for at least one hour, then beam and arch must be drenched by a plug stream of water, hose to be two and one-half inch, with a one inch nozzle, under a pressure of 65 pounds.

While fire is in operation the span of the floor must have a load of 750 pounds to the square foot resting on same.

The test must be witnessed, and in charge of an officer of this board."

The concrete appears to have stood this ordeal. The Board of Underwriters gave this certificate:—"As a result of the test of your concrete construction, witnessed by us on the 21st inst., I beg leave to say that we are satisfied with that type of construction for fire-proof buildings." This was signed by Mr. Biggert, assistant secretary of the Board, and addressed to the Columbian Fire-proofing Co., which has the contract for the work at the Simpson building. We understand it is the intention of the company to make some tests in Toronto, and that they desire to make it competitive, so that the relative merits of their system and others may be compared.

An important inquiry is about to be instituted in New York with the object of determining the value of various so-called fireproof materials, which will throw new light on the subject.

Some of the architects whose opinions we have sought say that their knowledge is only theoretical, but they cannot see why concrete, made with slag, should not be a good fire resistant. One, who used concrete for a hearth in a private dwelling, had an experience which rather surprised him, and which showed that it is not a good non-conductor of heat—a fact not very favorable to its fireproofing qualities. Others declare terra cotta, or preparations of clay, to be the only fire-resistants which can be depended on.

A recent test in Glasgow goes to show that concrete made with diatomite, which comes from the island of Skye, and consists of fossilized aquatic plants, will successfully resist fire.

It is claimed for concrete that in addition to being fire-resisting in itself, it possesses a great advantage so far as strength is concerned. And here let us correct a slight mis-statement in our former reference to the Simpson building. The spaces between the floor beams are filled in, not with hollow blocks of concrete, but with two thicknesses, having a space between. There are no joints—the concrete forms a monolith—and it is formed around iron bars which give it great strength. In this respect an advantage is claimed over terra cotta, in that the latter has to be put in place block by block, and being brittle, if one block is broken away, in a fire or otherwise, those beside it are liable to be dislodged. Certainly the tests applied to the concrete, as indicated in the Underwriters' requirements referred to above as well as other tests, show it to be possessed of great strength.

The ARCHITECT AND BUILDER simply seeks to give the facts, with a view of determining, as far as possible, what is the best fire-resisting material for buildings. That point it seems to be difficult to settle. The School of Practical Science at Toronto, part of whose work it is to test structural materials, is at present engaged with the matter, but has not as yet arrived at any conclusion. As a thoroughly disinterested investigator the result of its experiments will carry much weight. Would it not be well to employ more freely the facilities which that institution offers for testing materials about the merits of which there is great difference of opinion?

As the authorities differ on the point which has been raised by "Architect's" letter, we shall be pleased to have more light thrown upon it in the form of further discussion.

WHAT IS A FIREPROOF BUILDING?

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—Having read an article which appeared in the last number of the ARCHITECT AND BUILDER, referring to the method of construction adopted in connection with the new Simpson building, Toronto, I desire to protest against some of the statements contained therein.

The article states that "the building is practically indestructible by fire," and then proceeds to describe the method of fireproofing which is being employed, which consists of covering the beams with slabs of concrete, and surrounding the columns with the same material. I quite agree with the writer of the article when he states that "so-called fire-proof buildings have shown that they are not such in great conflagrations," and I have little hesitation in saying that should the Simpson building again become the object of a conflagration, it would prove to be no exception to the above mentioned rule.

Concrete in itself is not a fireproof material, and therefore a building in the construction of which it is used as such cannot be fireproof. It is a well known fact to those familiar with the nature of concrete that its character is changed by the action of fire, which burns out the lime in the material and also causes it to crack and disintegrate, as the result of contraction and expansion. No doubt concrete used in the manner described is in some degree a protection against fire, but it is valuable for this purpose only to a limited extent. A fireproof building should mean an indestructible building, and such a building cannot be constructed of iron covered with concrete.

I have made a careful study of the nature and adaptability of this material, and as a result I never use it in close proximity to steam boilers, or in any other position where it would be exposed to the action of intense heat. For such positions I use hard burned brick, or fire brick. So far as my experience goes, clay is the only material which will withstand the action of fire, and porous terra cotta is the only material which can properly be called fireproof.

I call attention to this matter with the object of endeavoring to dispel some of the ill-founded opinions which exist on the part of architects and the public, with regard to this subject. It is quite time that both architects and the public should clearly understand what constitutes a fireproof building. Only evil can result from misconception of facts, such as there is every reason to believe exists at the present time.

ARCHITECT.

THE fourth annual meeting of the Association of Ontario Land Surveyors will be held in Toronto, commencing on Tuesday, Feb. 25, 1895.

THE TORONTO TECHNICAL SCHOOL.

UNDER the new principal recently appointed the Toronto Technical School appears to have entered upon a fresh era of prosperity. As several new subjects have been added, some of them of great importance in the line of architecture and building, a resume of the history and work of the institution will be of interest.

The school was established in January, 1892. Its principal promoters were the late ex-Ald. Gillespie, who died before it was opened; Dr. J. Oriland Orr, the present chairman of the Board, who was the first chairman; the late Mr. J. A. Mills, and Mr. A. M. Wickens.

At first it was thought to be somewhat of an experiment, but the success already achieved has placed it in a more definite position. It is situated on College St., at the head of McCaul St., and directly to the south of the School of Practical Science, in what was formerly Wycliffe College. Permanent quarters have been secured there, and the building so fitted as to be better adapted to the requirements of the school.

It is maintained entirely by the city of Toronto, and is under the control of a Board of Directors composed of seventeen members. Five of these are members of the City Council, five represent the Trades and Labor Council, two the Stationary Engineers, two the Architects, two the Educationists and one the Manufacturers. Regular meetings of the Board are held on the fourth Tuesday in each month during the session, which begins with October and ends with April.

DR. McMASTER,
Principal Toronto Technical School.

The classes are free to all residents of the city who wish to avail themselves of its privileges. Both sexes are admitted. The course of study to be pursued by any one is optional, and registration and entrance to any class can be made at any time during the session. It is desirable, however, to enter the classes at the opening of the session.

The school has a staff of nine teachers, and the class hours are from 7:45 to 9:45 p.m. each week day evening, excepting Saturdays.

The design of the school is to aid those who have not had the advantage of an education in the early period of life. It is specially intended for the artizans, tradesmen, mechanics, etc., and those who follow the usual occupations of an industrial community.

The nature of the work done is very different from that usually taken up by the ordinary commercial colleges or schools. An enumeration of the subjects taught will give some idea of the work it is doing. They are: Arithmetic and Mensuration, Algebra, Euclid, Descriptive Geometry, Perspective Drawing, Mechanics, Chemistry, Practical Chemistry, in each of which there are both junior and senior classes. Besides these there are courses as complete as the time will permit in Applied Electricity, Heat, Hydrostatics, Steam and the Steam Engine, Hydraulics, Light, Sound, Practical Geometry, Freehand Drawing and Designing, Mineralogy and Geology, and Modelling in Clay. In the draughting room a numerous group of subjects is taken up, as Machine and Architectural Drawing, Industrial Design, Shading, Lettering, Machine Construction, etc.

That the school is doing an important and useful work, and that it is appreciated by the young men of the city, is attested by the fact that the aggregate attendance for last year was 631, while the average nightly attendance for the whole session was 286. This year the attendance is already about 450.

There are no fees for attendance on any of the classes, and each student can take any subject he chooses, or any group of subjects that the time table will permit.

Considerable improvement was made during the holidays by the remodelling of the building and the addition of new class-rooms.

The school is now fairly well provided with apparatus in the more important departments for the practical illustration of the various physical subjects taught. It is intended to make the teaching as practical as possible, and to see that the students know the work and not merely see it done. At the end of the session, or of the work in any subject, examinations are held in the various branches, and certificates are granted to those who succeed. A diploma is also given by the school to those who complete certain definite courses of study. This work, it is thought, will require from three to four years on the part of a student with average ability and but meagre attainments at his entrance upon the course.

Three new teachers have recently been appointed to the staff, and one of the old teachers, Dr. J. McMaster, selected as principal. The new teachers are Mr. James Milne, electricity and steam engine, Mr. D. Hull, mathematics, and Mr. A. W. White, draughting. There are now three instructors in draughting, Mr. E. R. Babington, who also takes modelling, Mr. A. F. McCallum and Mr. White.

Modelling is a new subject and has been added for industrial work. It is well to emphasize the fact that the instruction given by the school is not considered from the side of art, but industrial. It is not intended to train the æsthetic ideas of the pupils so much as to enable them to earn dollars. The class in modelling is at present engaged on the five orders of architecture and is intended for stone cutters.

We subjoin a brief sketch and portrait of Dr. McMaster, the new principal.

John McMaster, B. A., M.D.C.M., the subject of this brief sketch, was born in the county of Simcoe, Ont., in 1857. His parents, who were of Irish lineage, settled in that county a few years earlier. From the age of five till he was twelve, he was as regularly kept at school as the average boy in a newly settled country place can be. At that very early age he learned to plough and became so useful on the farm that he was kept at home, excepting for a few months in the winter. At the age of eighteen it was necessary for him to leave home and to earn a livelihood for himself. At this time his education was very meagre, being confined to reading, writing and arithmetic, at the latter of which he was somewhat expert. As a boy he was very ingenious with his knife, always being mechanically inclined. In spare time, and on wet days, he used to occupy himself making miniature saw-mills, to be driven by a small stream that ran through the farm. Fire-arms made of lead, and bows and arrows of every description, were among his numerous inventions. His desire as a youth was to be an engineer and machinist. In this he never had his father's support, and as he grew older he became more anxious to obtain an education. His first employer owned a small saw-mill and worked a farm besides. John was part of the time engaged in the mill and part on the farm. During this year he bought books and studied Euclid, History and Short Hand Writing. With the money he earned he resolved to begin his own education. After six months in a public school he passed the entrance to the high school, and very shortly afterwards—three months—obtained a second class B certificate. His means being exhausted, he again went to work, and soon secured enough to fit him for teaching. He attended the various training institutions for teachers in this country, and has been engaged in teaching in nearly all the different kinds of schools in the Province. By alternately teaching and studying he was enabled to secure all the different grades of certificates granted by the education department. A degree in arts was the next desideratum. At Toronto University he took a complete honor course in mathematics, graduating in physics in 1886. While there he did not confine himself exclusively to mathematics, but gained a fair knowledge of science, metaphysics and English literature. After graduating he taught mathematics and physics for a few years in different high schools in the province. Not being satisfied with his attainments, he resolved to take up the study of medicine. At Trinity Medical College he took the regular course in medicine, graduating at Trinity University in the spring of 1894. While an undergraduate in medicine he won considerable distinction among his classmates as a student, carrying off his full share of scholarships and prizes.

Before the Technical School began he was engaged as a teacher in the city night schools for several years, and when that institution was commenced in Jan. '92 he was engaged as one of the teachers. Since that time he has remained on the staff, chiefly being engaged in teaching mathematical subjects. The principalship of the school was declared vacant at a Board meeting in August last, and after duly advertising for applications to fill the position, Mr. McMaster was selected from among a number who applied. His duties as principal began at the opening of the school on the 1st of October.

Judging from his active and energetic disposition, and his varied experience in teaching gained in all kinds of schools, as well as his extensive attainments in the various scientific departments of education, we expect an unusual measure of success for this institution.

THE IRELAND BUILDING COLLAPSE.

THE grand jury in New York has found indictments for manslaughter in the second degree against the architect, inspector, clerk, contractor, superintendent and foreman mason of the Ireland building, which collapsed some time ago and killed fifteen people. This seems to be somewhat wholesale condemnation, but it is only right someone should be punished for a catastrope which was the result of carelessness, or worse, somewhere.

The grand jury in addition to the indictments, condemn the building department and its regulations and suggest a number of desirable reforms. The principal changes are as follows: That the soil upon which a building is to be erected shall be examined by a competent engineer, and a certificate filed with the department as to the unit of pressure per square foot the soil will sustain; that the department exercise a vigilant supervision by means of experts, over the laying of all foundations, and require a statement as to character and sufficiency of such foundations before the superstructure is proceeded with. The grand jury strongly condemn Mr. Ireland, censuring him for desiring to drive the best bargain possible, regardless of the safety and lives of the men imperilled by his penuriousness. It also points out that such catastrophe should be impossible in a civilized community, and its occurrence proves either a serious defect in the law or culpable negligence in enforcing it. The provisions of the law allow a load of four tons to the square foot on any soil. The jury think one or one and a half tons the limit of safety on soil of a weak and yielding nature.

The testimony at the inquest proved that the direct cause of the disaster was a reduction in the thickness of the concrete footing of the column which gave way, to less than one third of that indicated in the architect's plans and specifications. This shows that there was culpable negligence somewhere.

PUBLICATIONS.

The two architectural and engineering journals of Australia have recently been merged into one, which we trust will be handicapped by nothing but its title, viz., "The Building and Engineering Journal of Australia and New Zealand and Australian Builder and Contractors' News."

We are indebted to the Builders' Exchange of Philadelphia for a copy of their annual Hand Book and Catalogue. The book numbers upwards of 300 pages, and contains illustrations of the headquarters of the Exchange, portraits of past and present officers, the code of practice governing its members, a list of members, the building and sanitary by-laws of the city, and a vast amount of other equally useful information. The Philadelphia Exchange is perhaps the most progressive and prosperous local organization of builders on this continent.

Hon. Russel Sage and other New York capitalists, with Mr. H. H. McLean, of St. John, N. B., are applying for incorporation to take over the patents of the Gold Car Heating Co. for Canada.

Jeremiah O'Neill, of Toronto, is bringing a claim against the Hamilton Bridge Co. for $1,500 damages arising out of injuries received while employed on the construction of the Simpson building.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

ST. JEAN BAPTISTE EVENING CLASSES.

THE inauguration of evening classes organized by the St. Jean Baptiste Society for the benefit of those desirous of obtaining knowledge in the different branches of art and science opened last week in the Monument National. There were on the platform the Hon. Judge Loranger, in the chair; the General Consul of France, Mr. Kleczkowski; Messrs. J. C. Wilson, Judge Jette, J. X. Perrault, L. O. David, L. I. Boivin, Rev. Abbe Colin, S. C. Stevenson, G. Boivin, Hon. Jos. Royal, J. D. Rolland, Jos. Venne, A. Bonnin and Hon. A. Desjardins.

Messrs. Boivin & Wilson spoke on the teaching of arts and trades, and the professors of the different classes each presented the programme they intend to pursue during the coming season, and discoursed briefly at the same time on the various professions they represent. The following is a list of different classes, together with the names of their professors: Hon. Jos. Royal, Political Economy; L. O. David, Universal History; Jos. Venne, Architecture; J. X. Perrault, Agriculture and Colonization; A. Bonnin, Applied Science.

The teaching in the Architectural class will consist of a series of lectures twelve in number, accompanied by lime-light views, illustrations and special geographical maps. The dates of the lectures are not yet definitely arranged, but are expected to be within a few days. The following are the subjects to be taken up at each meeting: 1st, Cursory View of the History of India, Egypt and Assyria, illustrated by special geographical maps; 2nd, Building Construction in Stone and Brick; 3rd, Greece and Rome; 4th, Building Construction in Wood; 5th, The Middle Ages—the Gallo-Roman period; 6th, The Building Trades, of so-called secondary importance, such as copper, galvanized iron, lead, slate, marble, etc.; 7th, The Middle Ages—the Gothic period; 8th, The Modern Industries applied to Iron and Steel, and the Mode of Transportation, and Mechanical Execution; 9th, The so-called Renaissance period; 10th, Organization of Labor, ancient and modern; 11th, The Present Times; 12th, Retrospective Review.

The classes are entirely free of charge to everybody, and all are invited to attend the same, irrespective of condition and position.

MASTER PLUMBERS' ASSOCIATION.

As the result of a conference held recently between the wholesale dealers in plumbing and heating apparatus and the Executive Committee of the Master Plumbers' Association, a Joint Committee was appointed, consisting of Messrs. James Robertson, of Thos. Robertson & Co.; Mr. McLaren, representing the Toronto Radiator Co., and Mr. Lekyer, representing the Gurney-Massey Co., on the one side; and Mr. Jos. Lamarche, President, and Mr. G. W. Hughes, Corresponding Secretary, of the Master Plumbers' Association, on the other, to devise means whereby more satisfactory trade relations than have heretofore existed may be established.

COUNCIL OF ARTS AND MANUFACTURES.

The Plumbing Classes in connection with the Council of Arts and Manufactures will open shortly. The instruction, as in former years, will be given under the direction of a Committee appointed by the Master Plumbers' Association.

ARCHITECTS' ACCOUNTS.

The daily press having been discussing the two accounts of Messrs. Perrault & Mann, architects, rendered the city of Montreal for professional services, and which seem in the eyes of certain aldermen disproportionately high, a representative of your correspondent met one of the architects, with the object of securing enlightenment on the matter. It appears that the account in connection with the fever hospital is not, as many believe, for services in connection with the existing buildings on Moreau street, as there was no architect whatever for the erection of the building, everything being left in the hands of the contractors, but it is for the preparation of a set of plans, estimates, etc., for a new hospital containing 180 beds, and studies for same, together with the expense of a trip to the States for the purpose of visiting similar establishments there, in accordance with orders given jointly by the local and provincial health departments. As to the other account, the Market Committee having no fixed idea as to what it intended to do, had the architects prepare two sets of plans and specifications, which were considered by the Committee, but finally set aside, and for which the architects claim not to have received a cent. Their charges are only at the ordinary percentage rate on such work for the repairs of the market, which the Committee decided in the end to preserve.

OBITUARY.

An old-time Montreal plumber has recently passed away in the person of Mr. A. Lothian, who at the time of his death was upwards of 79 years old. Deceased came to Montreal from Scotland in 1842, and assisted in the construction of the city water works.

THE CITY AND THE C. P. R.

The understanding arrived at some time ago by the city and the C. P. R., under which a new passenger depot was to be erected in the east end, has been disturbed by the substitution of another plan for the one which accompanied the agreement.

STRENGTH OF BRIDGE AND TRESTLE TIMBERS.*

YOUR committee appointed to report on "Strength of Bridge and Trestle Timbers, with special reference to Southern Yellow Pine, White Pine, Fir and Oak," desires to present herewith, as part of their report, the very valuable data, compiled by the chairman of the committee, relative to tests of the principal American bridge and trestle timbers, and the recommendations of the leading authorities on the subject of strength of timber during the last twenty-five years, embodied in the appendix to this report and tabulated for easy reference in the accompanying tables I to IV.

The uncertainty of our knowledge relative to the strength of timber is clearly demonstrated after a perusal of this information, and emphasizes, better than long dissertations on the subject, the necessity for more extensive, thorough and reliable series of tests, conducted on a truly scientific basis, approximating as nearly as possible actual conditions encountered in practice.

The wide range of values recommended by the various recognized authorities is to be regretted, especially so when undue influence has been attributed by them in their deductions to isolated tests of small-sized specimens, not only limited in number, but especially defective in not having noted and recorded properly the exact species of each specimen tested—its origin, condition, quality, degree of seasoning, method of testing, etc.

The fact has been proved beyond dispute that small-size specimen tests give much larger average results than full-size tests, owing to the greater freedom of small selected test pieces from blemishes and imperfections, and their being, as a rule, comparatively drier and better seasoned than full-size sticks. The exact increase, as shown by tests and by statements of different authorities, is from 10 to over 100 per cent.

Great credit is due to such investigators and experimenters as Professors G. Lanza, J. B. Johnson, H. T. Bovey, C. B. Wing, and Messrs. Onward Bates, W. H. Pinley, C. B. Talbot and others, for their experimental work and agitation in favor of full-sized tests. Professors G. Lanza, R. H. Thurston and Wm. H. Burr have contributed valuable treatises on the subject of strength of timber. The extensive series of small and full size U. S. Government tests, conducted in 1880 to 1882 at the Watertown Arsenal under Col. T. T. S. Laidley, and more recently the very elaborate and thorough timber tests being conducted by the U. S. Forestry Division under Dr. B. E. Fernow, Chief, and Prof. J. B. Johnson of Washington University, St. Louis, afford us to-day, in connection with the work of the above-mentioned experimenters, our most reliable data from a practical standpoint.

The test data at hand and the summary criticisms of leading authorities seem to indicate the general correctness of the following conclusions :—

1. Of all structural materials used for bridges and trestles, timber is the most variable as to the properties and strength of different pieces classed as belonging to the same species, hence impossible to establish close and reliable limits of strength for each species.

2. The various names applied to one and the same species in different parts of the country lead to great confusion in classifying or applying results of tests.

3. Variations in strength are generally directly proportional to the density or weight of timber.

4. As a rule, a reduction of moisture is accompanied by an increase in strength ; in other words, seasoned lumber is stronger than green lumber.

5. Structures should be, in general, designed for the strength of green or moderately seasoned lumber, of average quality, and not for a high grade of well seasoned material.

6. Age or use do not destroy the strength of timber, unless decay or season-checking takes place.

7. Timber, unlike materials of a more homogeneous nature, as iron and steel, has no well defined limit of elasticity. As a rule it can be strained very near to the breaking point without serious injury, which accounts for the continuous use of many timber structures with the material strained far beyond the usually accepted safe limits. On the other hand, sudden and frequently inexplicable failures of individual sticks at very low limits are liable to occur.

8. Knots, even when sound and tight, are one of the most objectionable features of timber, both for beams and struts. The full-size tests of every experimenter have demonstrated, not only that beams break at knots, but that invariably timber struts will fail at a knot or owing to the proximity of a knot, by reducing the effective area of the stick and causing curly and cross-grained fibres, thus exploding the old practical view that sound and tight knots are not detrimental to timber in compression.

9. Excepting in top logs of a tree or very small and young timber, the heart-wood is, as a rule, not as strong as the material farther away from the heart. This becomes more generally apparent, in practice, in large sticks with considerable heart-wood cut from old trees in which the heart has begun to decay or been wind-shaken. Beams cut from such material frequently season-check along middle of beam and fail by longitudinal shearing.

10. Top logs are not as strong as butt logs, provided the latter have sound timber.

11. The results of compression tests are more uniform and vary less for one species of timber than any other kind of test ; hence, if only one kind of test can be made, it would seem that a compressive test will furnish the most reliable comparative results.

12. Long timber columns generally fail by lateral deflection or "buckling" when the length exceeds the least cross-sectional dimension of the stick by 20, in other words, the column is longer than 20 diameters. In practice the unit stress for all columns over 15 diameters should be reduced in accordance with the various rules and formulae established for long columns.

13. Uneven end-bearings and eccentric loading of columns produce more serious disturbances than usually assumed.

14. The tests of full-size long compound columns, composed of several sticks bolted and fastened together at intervals, show essentially the same ultimate unit resistance for the compound column as each component stick would have if considered as a column by itself.

15. More attention should be given in practice to the proper proportioning of bearing areas ; in other words, the compressive bearing resistance of timber with and across grain, especially the latter, owing to the tendency of an excessive crushing stress across grain to indent the timber, thereby destroying the fibre and increasing the liability to speedy decay, especially when exposed to the weather and the continual working produced by moving loads.

The aim of your committee has been to examine the conflicting test data at hand, attributing the proper degree of importance to the various results and recommendations, and then to establish a set of units that can be accepted as fair average values, as far as known to-day, for the ordinary quality of each species of timber, and corresponding to the usual conditions and sizes of timbers encountered in practice. The difficulties of executing such a task successfully cannot be overrated, owing to the meagreness and frequently the indefiniteness of the available test data, and especially the great range of physical properties in different sticks of the same general species, not only due to the locality where it is grown, but also to the condition of the timber as regards the percentage of moisture, degree of seasoning, physical characteristics, grain, texture, proportion of hard and soft fibres, presence of knots, etc., all of which affect the question of strength.

Your committee recommends, upon the basis of the test data at hand at the present time, the average units for the ultimate breaking stresses of the principal timbers used in bridge and trestle constructions shown in the accompanying table.

In addition to the units given in the table, attention should be called to the latest formulae for long timber columns, mentioned more particularly in the appendix to this report, which formulae are based upon the results of the more recent full-size timber column tests, and hence should be considered more valuable than the older formulae derived from a limited number of small-size tests. These new formulae are Professor Burr's, App. I.; Professor Ely's, App. J.; Professor Stanwood's, App. K.; and A. L. Johnson's, App. V., while C. Shaler Smith's formulae will be better understood after examining the explanatory notes contained in App. L.

Attention should also be called to the necessity of examining the resistance of a beam to longitudinal shearing along the neutral axis, as beams under transverse loading frequently fail by longitudinal shearing in place of transverse rupture.

In addition to the ultimate breaking unit stress the designer of a timber structure has to establish the safe allowable unit stress for the species of timber to be used. This will vary for each particular class of structures and individual conditions. The selection of the proper "factor-of-safety" is largely a question of personal judgment and experience, and offers the best opportunity for the display of analytical and practical ability on the part of the designer. It is difficult to give specific rules. The following are some of the controlling questions to be considered.

The class of structure, whether temporary or permanent, and the nature of the loading, whether dead or live. If live, then whether the application of the load is accompanied by severe dynamic shocks and pounding of the structure. Whether the assumed loading for calculations is the absolute maximum, rarely to be applied in practice, or a possibility that may frequently take place. Prolonged heavy steady loading, and also alternate tensile and compressive stresses in the same piece, will call for lower averages. Information as to whether the assumed breaking stresses are based on full-size or small-size tests or only on interpolated values, averaged from tests of similar species of timber, is valuable in order to attribute the proper degree of importance to recommended average values. The class of timber to be used and its condition and quality. Finally, the particular kind of strain the stick is to be subjected to, and its position in the structure with regard to its importance and the possible damage that might be caused by its failure.

In order to present something definite on this subject, your committee presents the accompanying table, showing the average safe allowable working unit stresses for the principal bridge and trestle timbers, prepared to meet the average conditions existing in railroad timber structures, the units being based upon the ultimate breaking unit stresses recommended by your committee and the following factors-of-safety, viz :

Tension, with and across grain	Ten.
Compression, with grain	Five.
" across grain	Four.
Transverse Rupture, Extreme Fibre Stress	Six.
" Modulus of Elasticity	Two.
Shearing, with and across grain	Four.

In conclusion your committee desires to emphasize the importance and great value to the railroad companies of the country of the experimental work on the strength of American timbers being conducted by the Forestry Division of the U. S. Department of Agriculture, and to suggest that the American Association of Railway Superintendents of Bridges and Buildings endorse this view by official action, and lends its aid in every way possible to encourage the vigorous continuance of this series of government tests, which bids fair to become the most reliable and useful work on the subject of strength of American timbers ever undertaken. With additional and reliable information on this subject, far-reaching economies in the designing of timber structures can be introduced, resulting not only in a great pecuniary saving to the railroad companies, but also offering a partial check to the enormous consumption of timber, and the gradual diminution of our structural timber supply.

POSSIBILITY OF SIMPLE AND SAFE HOUSE PLUMBING.*

By Herbert J. Bowman, C. E., Town Engineer, Berlin.

French Gothic Panel.

Mr. President and Gentlemen: — In the Statutes of Ontario, 47th Victoria will be found "The Public Health Act, 1884, and appended thereto a by-law, the enactments of which are in force in every municipality till altered by the Municipal Council.

Sections 15 and 16 of this by-law are practically the plumbing regulations in force all over the Province, except in the cities and towns that have adopted plumbing regulations of their own.

In order to see whether they are so framed as to admit of the "Possibility of Simple and Safe House Plumbing," it may be interesting to examine these enactments, which are as follows:—

Sec. 15. The following regulations regarding the construction of houses shall be in force within this municipality:

Rule 1.—No house shall be built in or upon any site, the soil of which has been made up of any refuse, unless such soil shall have been removed from such site, and the site disinfected, or unless the said soil shall have been covered with a layer of charcoal, covered by a layer of concrete at least six inches thick and of such additional thickness as may be requisite under the circumstances to prevent the escape of gases into such proposed house.

Rule 2.—The drain of every house which may be connected with a sewer or cess-pool shall be ventilated by means of a pipe extending upward from the highest point of the main soil or waste-pipe, and also by a pipe carried upward from the drain outside the walls of the house according to the principles shown in the appended diagram. These pipes shall be of the same dimensions as the said main soil or waste-pipe, and shall be constructed of the same material or of stout galvanized iron, and no trap shall intervene between the said ventilating pipes. In case a trap shall intervene between the sewer or cess-pool, and the ventilating pipes already described, then a four inch ventilating pipe of the same material as above described shall be carried from a point between such trap and the sewer. All such ventilating pipes shall be carried above the roof of the said house, and shall open above at points sufficiently remote from every window, door, sky-light, chimney or other opening leading into any house.

No pipe carrying air or gas from any drain or soil-pipe shall be connected with any chimney in a dwelling house, unless the same be a furnace chimney used exclusively for the purpose of ventilating such soil pipe or drain.

Rule 3.—Every house drain shall be constructed of vitrified earthenware or iron pipe; and every soil and waste pipe, of iron pipe rendered impervious to gas or liquids, the joints thereof being run with lead and caulked, or of lead pipe weighing at least 6 lbs. to the square foot; and the waste pipe from every closet, sink, tub, wash-basin, safe or other service shall have as near as may be to the point of junction with such service a trap so constructed, vented and furnished, that it shall at no time allow of the passage of gas into such house. All joints shall be so constructed as to prevent gas escaping through them.

Rule 4.—The construction of any closet or other convenience which shall allow of the escape into the house of air or gas which has been confined in any part of it or from the drain or soil pipe, is hereby prohibited.

Rule 5.—No refrigerator waste shall be allowed to connect with any drain.

Rule 6.—No pipe supplying water directly to a water-closet or urinal, shall be connected with the pipe supplying water for drinking purposes.

16. Every person who erects, or causes to be erected, any building shall, within two weeks of the completion thereof, deposit in the registry office of the registry division in which the building is situated, plans of the drainage and plumbing of the same as executed; and in the case of any alteration of any such plumbing or drainage, it shall be the duty of the owner of the house, within two weeks of the making of the alteration, to deposit in the same manner the plan and record of any such alteration; if such alteration is made by a tenant, it shall be the duty of the tenant or lessee to deposit, or cause to be deposited the plan and record of such alteration.

In examining these statutory plumbing regulations it must be remembered that they were compiled at least as far back as 1884, and that since that time considerable progress has been made toward simple and at the same time safe plumbing, and the methods of good plumbing practice have become more uniform.

Upon looking at the diagram appended to the Health Act, it will be seen that a trap is placed on the drain between the house and the sewer, but it is also indicted by the dotted lines that this trap may be omitted. Thus it will be seen that the views of both the opposing schools of plumbing experts have been met, one insisting upon a trap on the house drain and the other insisting that no such obstruction should be placed there.

The diagram, however, can scarcely be taken as illustrating a typical Canadian house, as comparatively few houses have two bath rooms.

It would have been better to have shown the necessary arrangement for a kitchen sink on the ground floor and also to have shown the cellar excavated, as is now usually done under the greater part of the house, affording a convenient place for the laundry with its stationary wash tubs or the less expensive slop hopper.

Rule 1, dealing with the soil of building sites, does not come within the scope of our present inquiry, so it may be passed over.

Rule 2 requires the extension upwards of the soil pipe (a) through the roof, but goes on to state that this extension may be of galvanized sheet iron. A sheet iron pipe is a cheap and temporary make-shift and should not be allowed in connection with house plumbing. Nothing but cast iron soil pipe and lead or brass waste-pipe are now used in good plumbing. This rule requires an outside ventilating pipe (b); which is quite unnecessary where no trap is placed on the house drain, and where a trap is used, this ventilating pipe, then called the fresh air inlet, is not usually extended above the roof, but only about two feet above the ground. It is very unlikely that the fresh air inlet would act at all were it constructed bending over the roof as shown in the diagram. This rule calls for still another ventilating pipe (c) in case a trap is placed on the main drain. This pipe is to be carried from a point between the trap and the sewer and extend up above the roof, and is an outlay placed upon the householder to ventilate the public sewer. Any bend in this pipe, as shown in the diagram, will cause it to freeze up during our Canadian winters, and even a straight pipe will sometimes freeze up at the top. Partly on account of this, but perhaps more on account of the additional outlay, from which the householder receives no benefit, the pipe is usually omitted in Ontario.

In most of our cities and towns having plumbing regulations of their own it is now required, or permitted, that a house have but one continuous iron soil pipe from the outer connection with the house drain at least three feet outside the wall, up to the opening at least four feet above the roof, the trap and other ventilating pipes being dispensed with. This is certainly the simplest arrangement and quite as safe as any other. It would be better to cut out the proviso that closes this rule and leave it "No pipe carrying air or gas from any drain or soil-pipe shall be connected with any chimney of a dwelling house."

Rule 3 requires that every house drain shall be constructed of vitrified earthenware or iron pipe. By house drain is evidently meant the private drain connecting the house plumbing system with the public sewer, and vitrified clay sewer pipe is almost invariably used, as outside of the house it answers the purpose equally as well as cast iron pipe and costs less than one quarter as much. Inside the house, however, nothing but cast iron soil pipe and lead and brass waste-pipe should be used. The minimum weights per lineal foot for the different sizes of lead waste-pipe should be given, as nothing but drawn lead pipe is now used. The old method of making lead waste-pipe by hand from sheet lead has been entirely discarded, so that the rule should be amended where it says "lead pipe weighing at least 6 lbs. to the square foot." The requirement that iron pipe shall be rendered impervious to gas or liquids was probably inserted in this rule to ensure a liberal coating of coal tar to the cast iron soil pipe. It has been found, however, that the coal tar varnish covered up sand-holes and other defects in the pipe, so that now untarred pipes and fittings are mostly used after having been immersed in linseed oil to prevent them from rusting. The only proper way to render cast iron soil pipe impervious to gas or liquids is to require a good thickness of metal, and a standard for the different sizes should undoubtedly be laid down in the Public Health Act. This would please the manufacturers, because they would require but one set of patterns; it would please the wholesalers because they would require to stock only the standard sizes; it would please the master plumbers because they would then not fear the dishonest rival underbidding on light pipe; it would please the plumber because it would lessen the danger of having to remove cracked pipes and fittings when the water-test is applied; and last of all it would be a great benefit to the householder, as he would have the foundation of a good plumbing job ensured.

The requirement that the waste from every fixture should be trapped and vented, is a good general rule, although there are some cases where trap vents are not necessary. The word "safe" must have crept into the list of fixtures unawares, as it has long been considered a violation of the rules of good plumbing to connect a safe-waste direct with any drain. Safes of sheet lead were usually placed under the old fashioned boxed-in plumbing fixtures to prevent water from leaky or defective baths, etc., going through the floor and injuring the ceiling below. It is quite possible that sufficient water might never be caught in a safe to fill a trap on its waste, hence it should not be connected direct with the plumbing system, but empty openly into some lower fixture. Fortunately safes are now seldom required since all fixtures are left open and if any water leaks onto the floor it may be easily seen and mopped up. The conclusion of rule 3 is somewhat indefinite, viz: "All joints shall be constructed so as to prevent gas escaping through them." The section of the Toronto plumbing by-law governing this matter is much more practical and is as follows: "Every connection between lead and iron pipes shall be made with brass thimbles or ferrules, having properly wiped joints, and the ferrules shall be properly gasketted, leaded and caulked into the said pipe. Ferrules for four-inch pipe shall weigh not less than two and a half pounds; for three inch pipes not less than one and three quarter pounds, and for two inch pipes not less than one and a half pounds; each ferrule to be not less than four inches in length. All lead pipes shall have properly wiped joints. When the trap to closets is above the floor, the connection of the same with the soil-pipe shall be made of brass and rubber, said brass flange to be not less than three sixteenths of an inch thick and cast."

Rule 4 is a good general rule, but, in spite of it, the writer has recently found in one of our Ontario towns a new plumbing job with the universally condemned pan closet fitted up. The water closet is perhaps the most important plumbing fixture in a house and the styles made are innumerable, although but two types of closets are now generally used. The older of these is the "hopper" closet, consisting of a straight hopper discharging into an S trap, and forming a good closet from a sanitary point of view, although objected to by the fastidious as its walls are not easily kept clean without almost daily attention. In an attempt to remove this objection, the wash out closet was designed, being in reality a distorted hopper discharging into the same form of trap. This arrangement does not remove the filth, but puts it out of sight and where it is more difficult to get at. The true solution of the problem was the construction of a hopper closet in one piece with the walls more nearly perpendicular, and a larger and deeper pool of water in the trap. This forms what has been termed the "wash-down" closet now coming into general use. The remaining type of closet is used in more expensive work and is composed of the various forms of "syphon" closets. These have deep pools of water and have various devices to start syphonic action to remove the contents rapidly.

Tinned copper baths are now the most frequently used, and when "steel-clad," require no work around them and are just as good from the sanitary standpoint as enamsled cast iron or the expensive porcelain baths. The ordinary porcelain basin is defective because there is no means of cleaning the overflow pipe. A removable strainer on the overflow is much more desirable. Kitchen sinks of cast iron, steel and porcelain are in common use. The waste pipe from an ordinary kitchen sink should not be more than 1½ in. in diameter and have an ordinary lead trap properly vented to prevent the seal being syphoned out when the rush of water goes down the soil pipe from the closet.

Rule 5 is a wise one, as no refrigerator waste should be connected direct with the plumbing system. During the winter no ice is placed in the box and the water seal of the trap would soon be lost. There is no objection, however, to have the waste water from the refrigator discharged openly into the kitchen sink or into any plumbing fixture in the basement below, or it may discharge into the trap on the cellar drain. No mention seems to be made in the rules of how cellar drainage should be arranged where it is required.

Rule 6 is intended to prevent contamination of the drinking water in case the water should be turned off in the street main and a partial vacuum thus caused.

Section 16, requiring owners of houses to file in the county registry office plans of the drainage and plumbing of same as executed, seems to be entirely ignored. House plumbing should be constructed so that every detail may be easily examined without a plan, but of course a plan of the outside drainage should be on record somewhere, and if every town had a registry office no better place could be found.

From the foregoing comments the conclusion may be drawn that when the statutes are revised in 1897 some changes and additions are required to bring this portion of the Public Health Act up to date.

* Paper read at annual meeting of Medical Health officers for Ontario, Sept., 1895.

TORONTOS' MUNICIPAL BUILDING.

In a report submitted to the Property Committee of the Toronto City Council a few days ago, Mr. Lennox, architect of the new court house, strongly urged that an iron roof be substituted for the wooden roof shown on the original plan. He pointed out that the building was substantially fire proof, and that a fire could only spread by means of the roof, and that in the event of the timbers becoming ignited, the flames would be uncontrollable at such a height. The character of the neighborhood was, he thought, a great element of danger. He pointed out that iron and fire proof material was fifty per cent. cheaper than when the estimates for the building were prepared.

As to cost, while several plans were proposed, he strongly advised one with steel principals, and beams, and steel rafters, riveted together, and porous terra cotta protection. This, allowing for the reduction in carpenter work by the change, would increase the cost $27,702. An alternative plan was mentioned, to have the roof of slowly burning construction, by having 3½ inch plank protection instead of terra cotta. This would cost $18,202.

When the report came up in the committee for consideration it was determined not to make the change, but Mr. Lennox was instructed to report on the cost of a covering of asbestos under the tiles, and also on the cost of iron beams and marble floors in the corridors instead of wood beams and oak floors.

These further facts came out in the discussion: The stone work will cost about $100,000 over Elliott & Neelon's contract. The plumbing contract, including heating, is the only one not let. Mr. Lennox says he has an offer from one of the largest firms in the city to do it for $78,000 or $79,000. All the stone is now on the ground except about $10,000 worth. About $200,000 more is required for the work to carry it to completion. According to present estimates the total cost will be $1,850,000. Mr. Lennox says there will be no extras.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A CITY STORE FRONT.

THE competitions previously held under the auspices of the CANADIAN ARCHITECT AND BUILDER were especially designed to test the student's ability to properly design and plan various kinds of buildings. The object of the present competition is to test his knowledge of construction. It is to be feared that many students who have the ability to make pleasing sketches are less proficient as regards a knowledge of the character of materials and the proper methnd of employing them in building construction.

With the object, as stated, of bringing to the proof the knowledge of this character which they may possess, students of architecture residing within the Dominion of Canada are invited to submit competitive designs for a city front for a retail jewelry store on a leading street.

The building is to have a frontage nf 35 feet, and to be 5 storeys in height, with a retail store on ground floor, and a side entrance affording access to upper storeys, which are intended to be used for office purposes.

Drawings must be made with PEN and BLACK INK on WHITE cardboard, drawing paper and tracing cloth. On one sheet is required an elevation and plans of ground and first floors of the building, drawn to ⅛ scale; on another sheet, working details of ground floor, drawn to ¾ scale, and sufficiently coarse to admit of reduction to 15 x 10 inches in size.

Each competitor is require to mark his drawings with his nom de plume only, and to forward his drawings, so marked, postpaid, addressed to the editor of THE CANADIAN ARCHITECT AND BUILDER, Confederation Life Building, Toronto, at a sufficiently early date to enable them to reach their destination before 5 o'clock p.m. on the 3rd day of December next, at which time the competition will close.

Each competitor must forward with his drawings a sealed envelope, containing his nom de plume as it appears on his drawings, together with his full name and address, and a brief description of his design, stating the materials proposed to be employed in its erectinn.

The first premiun in this competition is $10.00, the second $5.00, and the third one year's subscription to the CANADIAN ARCHITECT AND BUILDER.

The competition will be decided by a Committee of three members of the Ontario Association of Architects.

THE CANADIAN ARCHITECT AND BUILDER reserves the right to publish any of the drawings submitted. All drawings will be returned to their authors within a reasonable time after the competition is decided.

Competitors are urged to pay strict regard to the above stated conditions. Drawings which do not conform to these conditions will not be considered.

THE REQUIREMENTS OF AN ARCHITECT'S EDUCATION.

THE President of the Architectural Association, in his address at the opening meeting of the Association in London last month, gave the following as the prevailing consensus of opinion regarding the main need of an architect's education: 1 That the system of pupilage or apprenticeship is good as far as it goes, but it does not go far enough. 2. That it should be supplemented by systematic training by skilled instructors. 3. That that training should be directed to stimulate the artistic faculty—to order the imagination, to give the necessary practical as well as theoretical knowledge in all the accessories of the craft; in short, should consist of work in studio, lectures, classrooms, and in workshop.

THE ORIGIN OF FINGER PLATES.

A CURIOUS custom introduced by our forefathers is that of finger plates for doors. It is a custom that is gradually disappearing, but one that dies hard. I have seen (says Ashby Sterry in the Graphic) superb old solid Spanish mahogany doors disfigured by a modern garish finger plate. As far as my experience goes, if one wishes to open or shut a door, one always takes hold of the handle. Probably everyone who happened to be sane or sober would take a similar course I have been endeavoring for some time to trace the origin of the aforesaid finger plates, and have come to the conclusion that they must have arisen from the intemperate habits of our ancestors. Probably when they were so disguised in liquor that they were unable to see the handle of a door, they usually laid hold of the edge at any part where they could conveniently clutch it. In that case the finger plate was doubtless of some service, and those made of corrugated brass, and very popular in days gone by, probably gave a very firm hold when people in general were glad to find something to cling to. But in the present mild days of lemon squash and sobriety, the finger plate is altogether an absurdity, and the sooner it is disestablished the better.

BUILDING MATERIALS SEVERELY TESTED.

IN a series of glass cases in the room of the Public Buildings Commission, at the city hall, Philadelphia, says the Philadelphia Record, are preserved a number of specimens of materials used in the construction of the building which have been subjected to a pressure test by the government machine at Watertown, Mass. A sample brick from those used in the construction of the tower still retains its shape, although compressed into powder by a pressure of 500,000 pounds to the square inch. Its mate, rather dilapidated, did not succumb until 600,000 pounds pressure was reached.

Specimens of the white marble which forms the imposing exterior nf the hall showed remarkable staying power. One cube successfully resisted a pressure nf 800,000 pounds, and a portion of a similar specimen is preserved which cracked only under the enormous pressure nf over 1,000,000 pounds. A report like a cannon shot was heard when it finally gave way, and the commissioners maintain that if a block of marble near the foundation of the city hall should crack, the report could be heard in Kensington.

USEFUL HINTS.

AN English writer gives the following as the best way to finish exterior hardwood: First, give the work a coat of clear raw oil, with the addition of a good paste drier. Let this stand several days to harden. Then thoroughly fill it with good filler, let dry, and then apply three coats of shellac, thorougly rubbing down in oil on each coat, and you will have a job which will last for years.

THE objectionable dark coating which most bronze statues soon acquire, with the look of cast iron, does not consist, according to Herr Buhl, of sulphuride of copper, as commonly supposed, but of a mixture of coal dust, sand, etc., with oxides of the bronze metals. It is not removable, either mechanically or by treatment with dilute sulphuric acid; but on the other hand, it may be very quickly and completely washed off by means of a concentrated solution of carbonate of ammonia, applied with brushes. Thereupon a layer of patina is formed, which guards the statue against fresh formation of the dark coat.

IT is very noticeable, says Edward Hurst Brown in Painting and Decorating, that the rich red shades are again coming into favor for certain sorts of interior decorations, more especially in halls and dining-rooms. Some very handsome papers are shown entirely in reds, in which the designs are self-colored, after the manner of brocades or damasks. Other old fashions that are again coming into use are the papers in imitation of old tapestries, with curious landscapes or pictorial effects, or quaintly colored flowers, highly naturalistic in their coloring, yet on the whole somewhat subdued and sombre, because the general color tone is dark rather than light. In another direction an old fashion is revived when we find papers on the market this season that very closely resemble the old gilts, with a powdering of single or double leaves, in shaded gold, on a plain tint background. There is a certain sweet simplicity about these that cannot fail to make them popular with a great many people who are tired of a great deal of the over decoration that has been done of recent years. The trouble too often has been that our houses have been decorated to death, and there has been no living in peace with eur walls.

HALIFAX SANITARY REGULATIONS.

THE Royal Gazette, the official paper nf Nova Scntia, contains the rules and regulations of the Board of Health, for the city of Halifax, for the guidance of architects, plumbers, householders and others using the water supply, to secure the sanitary condition of buildings. For purposes of comparison we reproduce them.

1. It shall not be lawful to construct or extend any drain for the reception of sewerage or waste water under or into any building, or to connect the same with any public or other sewer or drain, unless the said drain shall in its plan and construction conform to the following requirements:

(a) An effectual hand-hole cleaning trap, of approved description and make, shall be placed in line of drain or soil pipe just before it leaves the premises.

(b) Between the said trap and the foot of the soil pipe (to be situate as remote as possible from any opening into the house) there shall be connected with the main house drain an inlet pipe for the admission of fresh air, four inches in diameter, the mouth of which shall be left open and have a cap, giving an area of one-fourth more than the diameter of the inlet pine;

(c) All soil pipes within the walls of any building shall be of cast iron, and continue to at least three feet above any opening in the roof which may be within fifteen feet of same, and three feet above any opening into any adjoining building or extension, when such building or extension is within fifteen feet of such pipe, and be left open so that the whole of the inside drainage may be thoroughly and constantly ventilated. All soil or vent pipes, when they pass through the roof, must be properly flashed with 5 lb. sheet lead, and made water-tight.

(d) Whenever in the opinion of the plumbing inspector and the city engineer the trap provided for in section (a) would be liable to freeze, it may be dispensed with, and the fresh air inlet provided for in section (b) will not be required;

(e) The soil pipe shall have two cleaning out screws, one to be about twelve inches above and in front of the bend of the basement floor, and the other between the said bend and the outer wall of the house;

(f) All drains and plumbing fixtures of any house or other building shall be provided with sufficient traps and vents to prevent gas from the sewer, drain or waste pipes from escaping into any apartment, and each such fixture shall have its own trap, with sufficient vent; said trap to be placed directly under and as close as possible to fixture;

(g) No fixture shall drain through more than one trap (main trap excepted); the vent to be not less than one size smaller than trap, and no vent of less than one and one-quarter inches in diameter; all traps must be protected from syphonage by special vent pipe;

(h) No trap vent pipe shall be less than three inches in diameter where it passes through the roof, and all vent pipes must continue to rise after leaving the trap, and pass out through the roof or connect with the soil pipe;

(i) The rule for soil pipe terminus, as hereinbefore mentioned, shall govern said vent pipe;

(j) Vents of water-closet traps shall be two inches for a length of twenty feet and for a greater length three inches in diameter;

(k) No safe-waste, range boiler, refrigerator waste or cistern overflow shall be allowed to connect direct with any drain; the end of such wastes shall be covered by flap valves;

(l) Waste from bath and basin will not be allowed to connect to water closet bend, but must have a separate fitting or connection to receive the same, except where the bend is iron and situated below the ceiling;

(m) The waste pipe of bath, basin or any fixture shall not be connected with the trap of a water closet or any other fixture. Exit pipes of all fixtures, except water closets, shall be furnished with suitable attached strainers. Overflow pipes from fixtures must in each case be connected on the inlet side of the trap.

(n) The overflow pipe from the water closet cistern shall not be directly connected with the soil pipe of any fixture;

(o) No pan closet shall be fitted up in any building, and no closet or other convenience which allows the escape into the house of air or gas which has been confined in any part of it, or from the drain or soil pipe, or which allows the accumulation of filth in or about it, shall be fitted up or used;

(p) Sinks in all hotels, restaurants, boarding houses, laundries, or other places where the engineer or inspector of plumbing or other officer approved by the Board may direct, shall be provided with suitable grease traps.

2. Each house or building must have its own separate soil pipe and drain, and such soil pipe or drain shall be so placed as to be always readily inspected without destruction to walls, and the plumber shall be responsible for the proper connection of his work with the system of drainage, which connection shall be made by a cast iron bend and five feet of pipe extending horizontally from the vertical soil pipe, and no two or more houses or buildings shall have a drain in common until such separate drain passes outside the walls of the house or building which it serves. Where buildings are constructed flush with the line of the street two buildings may be connected with one six-inch or larger street drain with a Y junction placed immediately in front of wall. All drains must be properly connected with the private drain, and not covered until inspected. In no case shall the drains between the walls of the house and the street line be laid until the private drain from the street line to the public sewer has first been laid and completed. Changes in direction of soil pipes shall be made with curved pipes, and connections with horizontal pipes shall be made with Y branches.

3. No iron pipe shall weigh less than the following per length of five feet:

6-inch diameter,	.....	100 lbs.
5-inch "	.....	85 "
4-inch "	.....	45 "
3-inch "	.....	30 "
2-inch "	.....	20 "

All pipes, traps, bends or fittings shall be of good quality, and shall be free from flaws or defects, and shall be of uniform thickness. No inverted joints of any kind will be allowed below any fixture.

4. Every connection between lead and iron pipes shall be made with brass thimbles or ferrules, having properly wiped joints, and the ferrules shall be properly gasketted, leaded and caulked into the said pipe. Ferrules for four-inch pipes shall weigh not less than 2½ lbs.; for three-inch pipe, not less than 1¾ lbs., and for two-inch pipe, not less than 1 1-2 lbs., each ferrule not to be less than four inches in length. All lead pipes to have properly wiped joints. Where the trap to closet is above the floor the connection of the same to the soil pipe shall be made of brass and rubber, said brass flange to be not less than three-sixteenths of an inch thick and cast.

5. No lead waste or vent pipe shall weigh less than the following:

1	inch in diameter....	6	lbs. per yard.	
1 1-4	" "	7	"	"
1 1-2	" "	8	"	"
2	" "	10 1-2	"	"
2 1-2	" "	13 1-2	"	"
3	" "	16 1-2	"	"
4	" "	24	"	"

Trap vent pipes may be standard iron, with steam fittings: sheet metal will not be allowed. All traps and fittings shall be equal in quality and thickness to the pipe to which they are attached.

FOR WATER SUPPLY PLUMBING.

6. Hereafter it shall be unlawful for any person (except the officers and servants of the city in the discharge of their duties) to attach, put in, lay or re-lay, introduce, extend or alter any water pipe, tap, fitting, apparatus or appliance, by or through which city water may be supplied, drawn, distributed or used, unless such person or his employer holds a license from the city as a duly authorised plumber for that purpose.

7. Application for laying of service pipes shall be made in writing at the city engineer's office and upon the required forms.

8. Every house or building separately assessed on the line of street is entitled to one-half inch service pipe. Where pipe is supplied larger than half-inch an extra charge will be made.

9. No two premises supplied with water from the water works shall be dependent upon one service pipe beyond the street line, but each separate and distinct tenement or premises shall be supplied through a separate pipe provided with proper stopcocks or other means of cutting off the water.

10. All service pipes upon the premises of water takers shall be laid at a depth of not less than five feet below the surrounding ground, and must not be turned up or laid at a less depth where they pass through or under a cellar wall or into or through any private premises, and where they cross or are near any other excavation, they must be properly protected against settlement.

11. In all cases the water taker must show that the pipe laid within his premises is laid in accordance with the requirements of the city, and unless the same is shown to the satisfaction of the city engineer, connection shall not be made with the street pipe.

12. When a service pipe has once been put into a house or premises by the city, the owner or occupant of the premises consenting, or not objecting, to the position of such service pipe, then no subsequent removal of such service pipe shall be made except at the expense of the owner, agent or occupant of the said premises.

13. For water works pressure no lead pipes shall weigh less than the following:

⅜-inch internal diam.,	4 lbs.	per lineal yard.	
½-inch	"	6 lbs.	" "
⅝-inch	"	8 lbs.	" "
¾-inch	"	10 lbs.	" "
1-inch	"	13 lbs.	" "

14. All water supply pipes shall be laid with due regard to danger from freezing, and be properly laid and graded, with a fall to a stop, and wastecock placed in the cellar or other convement point where they can be entirely drained off.

15. All pipes in buildings must be so laid and placed as to be easily accessible.

16. Water pipes or fittings on private premises must never be laid, carried along or put near any external wall, doorway or window opening, or in any exposed position or other position where they would be liable to freeze, without being thoroughly boxed in, encased or protected to the satisfaction of the city engineer, or his authorized officer, so as to prevent the action of frost.

17. If necessary to prevent freezing, the pipes must be carried at a sufficient depth underground below the cellar to some convenient point in the interior of the building, from thence the pipes must be properly encased in suitable boxing of ample size, stuffed with some suitable approved non-conducting material, the pipe being carefully placed and secured in the centre of the box.

18. In case of leaky or improper pipes or fixtures on any premises, the city engineer shall have authority to cut off the supply of water by shutting off the stopcock or by detaching the service pipe from the main, and before the water is again turned on the pipes and fixtures shall be repaired or altered as required, and the cost of detaching and re-attaching or of turning off and on the water shall be paid by the person owning or occupying the premises, and no person supplied from such service shall have any claim against the city by reason of such cutting off of the water.

19. Whenever any water taker has reason to fear that the water may freeze in any of the pipes or fittings on his premises, in spite of all precautions taken to prevent the same, he must be careful to see that the water is shut off from the premises at the stop and waste cock, and the pipes emptied of water, except when actually needed for use.

20. The fact of water being found running to waste from any pipe, tap or other water fitting will be held to be sufficient notice from the city engineer that the water is to be at once shut off from the premises as required by law. Water takers are cautioned that as a rule any noise heard in a pipe, even though no defects are visible, is an indication o

leakage and waste of water somewhere on the premises, and calls for immediate investigation and stoppage.

21. All persons shall keep their service pipes, stop-cocks and other fixtures on their own premises and from the line of the street in good order and repair, and protect from frost, at their own risk and expense.

22. Stop and waste cocks must on no account be covered up with coals, vegetables, or anything which will prevent the inmates of the house or the water inspector from getting access to them at once. And whenever any licensed plumber is called into any premises, his first care shall be to see that this rule is attended to, also to see that the stop and waste cock is in good order and easily turned.

23. Taps, faucets, cocks or fittings in porches or sheds, or outside of buildings are strictly prohibited. Any such supply required must either be by means of a suitable approved hydrant or by special written sanction of the city engineer.

24. The water supply to stables, barns, outbuildings or any other description of buildings or property must come under the operation of Rules 10, 11, 15, 16, 17, 21, 22, and 23, and must conform in all other respects with the requirements of these rules and regulations. If after every practicable precaution has been taken the pipes or fittings cannot be wholly and effectually protected against the action of frost in the severest weather they must be cut off and removed, or an approved hydrant with valve well below the reach of frost may be substituted in order to procure the required supply.

25. All urinals, except those which are especially sanctioned by the city engineer, and rated by the works department, shall either be supplied through a meter or shall have some approved valve or apparatus attached thereto, or in connection therewith, by which the same can be flushed, with not more than two gallons of water, at intervals not exceeding thirty minutes, or with not more than one gallon at each time of use.

26. After the 31st day of December, 1896, it shall be unlawful for any person whomsoever to have upon his premises, and connected with the city water supply pipes, any water closet which is not provided with a suitable and effective valve and cistern, or other substantial arrangement, approved by the city engineer, by which the water supply may be cut off automatically after flushing the closet with a quantity of water not exceeding three gallons each time it is used.

The remaining rules provide for permits, inspection, licensing of plumbers, appointment of inspectors and their duties, penalties, etc.

NEW PATENTS.

THE last issue of the Patent Record contains notice of the granting of a number of patents relating to architecture and building. Like so many of the patents taken out, some of them are of little practical utility, but we give a list, with some notes, so that if any of our readers wish to look further into them they may have the opportunity of doing so.

Water Closet—P. H. Howard, assignee of Wm. T. Fox, Rochester, N. Y.

Roofing Tile and Machinery for manufacture of same—Abraham Weil, Steinheim, Prussia. The claim in this case consists mainly in a packing consisting of a metal plate, which is slit and bent back, bringing about an intimate connection of the tiles and augmenting the durability of the roof.

Combined Screen and Storm Door—Chas. C. Wheeler, Holland, Michigan. This door is so made that wire screen can be used in summer and panels in winter on the same frame.

System of Heating Buildings—John D. McEachren, Galt, Ont. All the hot water is conveyed, by this system, from the heater to an expansion tank in the upper part of the building, whence it is distributed to the radiators.

Means of Applying Paints and Varnishes—H. C. Cleaver, London, England. This is a plan by which paint is sprayed from a tank by means of an air pump or compressor. It is substantially the plan adopted at the World's Columbian Exhibition buildings.

Window Screen—Chas. C. Wheeler, Holland, Michigan. This screen is so constructed as to permit of its extension to fit windows of different size.

Ladder—Thos. J. Quinn, assignee of Mark A. Walker, Detroit, Mich. Simply an extension ladder.

Hot Water Heating Apparatus—The Phoenix Hot Water Heater Co., assignee of S. N. Murgittroyd, Phoenix, N. Y. A new form of construction of hot water heater.

Machine for Bending and Trimming Metal Shingles—The Metallic Roofing Co. of Canada, assignee of C. W. Conner, of Montreal.

Cornice Mould Embracing Frame—Henry Burbidge, Kentville, Nova Scotia.

Hot Air Heating Apparatus—C. P. Shindler, Vancouver, B.C. This is a combination of a fire frame with an angular shaped coil.

Artificial Stone—Wm. Owen, London, England.

Sewer Pipe—Moise Courtemanche, Montreal. Means of securing opening in the side of sewer pipes.

Paving and Roofing Composition and method of making the same—The Asphaltina Co. of America, assignee of J. A. Just, Syracuse, N.Y. (3 patents). The first is for a composition made by adding resin and sulphur to petroleum sediment. The second is for a composition made of a calcium resinate, a heavy hydrocarbon, tar and sulphur. The third is for a composition made by treating tar with sulphur.

Method of Manufacturing Cement—Jasper Whiting, Chicago, Ill. Molten slag is chilled, dried and ground, and caustic soda or lime added to form this cement.

Warm Air Register—Charles H. Foster, Omaha, Nebraska. This register combines a frame, with guard, valve panel, foot rest and dust receptacle.

Sash Lift, Balance and Lock—F. H. Peters, Montreal. A sash lift, balance and lock in combination.

Metallic Shingle—Frederick Crawford, Toronto. A new form of metal shingle.

A NEW CANADIAN PAVING MATERIAL.

AN experiment has been made at Cleveland, Ohio, in the use of trap rock as a paving material, and it promises to result very satisfactorily. A foundation of crushed limestone, ten inches thick, is laid; above this is placed the trap rock, eight inches thick, arranged in three layers—coarse screenings, fine screenings and dust. The trap is obtained from quarries near St. Joseph's Island, St. Mary's River, at the north of Lake Huron. The rock can be had for little more than the cost of quarrying and transportation, and the pavement as laid down cost $3.10, $3.19 and $3.65 according to grade. Two miles have been laid in Cleveland and it promises well. Trap is used extensively in Germany for road making.

ARCHITECTS AND BUILDERS IN CONVENTION.

The American Institute of Architects held its twenty-ninth annual convention at St. Louis, during the third week of October. One of the matters considered was a classification of the membership into four grades, which was determined upon. The questions of education and the licensing of architects received much consideration. This we shall have occasion to refer to more fully at a future time. A permanent home for the Association is proposed, probably at the national capital, and a committee was appointed to deal with it. Fire protection was also considered, but the association seemed disposed not to take the initiative, and it was left in the hands of a committee. A number of interesting papers were read. The next convention will be at Nashville, Tenn.

The National Association of Builders met at Baltimore the same week. The greater part of the time was spent in rearranging the constitution, provision being made for state associations. Next year's convention will be held at Buffalo.

A WORKMAN'S SUIT FOR DAMAGES.

While working at the new court house in Toronto, on the 20th of September, 1893, Samuel Garland met with an accident, through a four ton stone falling from a derrick, whereby his foot was crushed. He sued the city for $3,000 damages, the case being tried before Judge Street in April, 1894. It resulted in a non-suit, but on appeal a new trial was ordered, and the case came up again recently before Judge Meredith. The jury was chosen entirely from the country, and the verdict was again in favour of the city. The plaintiff's foot had only one small bone broken, but it was so badly bruised that it will always be disabled.

One of the points involved was as to the method of lifting large stones at the building. It was the custom to raise them by means of chains placed around them, but in this instance the stone was lifted by dogs, which tore out and allowed it to fall. The evidence established, however, that the plaintiff and a man who was working with him, who was not a foreman or anyone he was bound to obey, were wholly responsible for the accident, and that therefore the city could not be held for damages.

The Toronto Radiator Mfg. Co. have recently erected extensive additions to their buildings on Dufferin street. The ground floor of the new buildings is conveniently fitted up as offices and show rooms, the upper floors being used for manufacturing purposes.

CANADIAN ARCHITECT AND BUILDER.

VOL. VIII.—NO. 12. DECEMBER, 1895 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1895.

PRESIDENT	FRANK DARLING, Toronto.
1ST VICE-PRESIDENT	THOS. FULLER, Ottawa.
2ND VICE-PRESIDENT	J. GEMMELL, Toronto.
TREASURER	H. B. GORDON, Toronto.

COUNCIL:

D. B. DICK	Toronto.
W. A. EDWARDS	Hamilton.
F. J. ALEXANDER	Ottawa.
J. M. MOORE	London
W. R. STRICKLAND	Toronto

REGISTRAR AND LIBRARIAN:

W. A. LANGTON — Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	A. C. HUTCHISON, Montreal.
1ST VICE-PRESIDENT	A. T. TAYLOR, Montreal.
2ND VICE-PRESIDENT	J. E. PEACHY, Quebec.
SECRETARY	J. VENNE, Montreal.
TREASURER	JOSEPH PERRAULT, Montreal.

COUNCIL:

CHAS. BAILLAIRGE	Quebec.
ROBT. FINDLAY	Montreal.
J. Z. RESTHER	Montreal.
A. H. LAPIERRE	Montreal.
G E. TANGUAY	Quebec
THEO. DAOUST	Montreal.

AUDITORS—A. J. FOWLER and C. CHAUSEE, Montreal.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

GEO. OAKLEY, President.
JOHN ALDRIDGE, 1st Vice-President.
WM. PARK, 2nd Vice-President.
DAVID WILLIAMS, Treasurer.
JAS. CRANG.
WM. PEARS.
FRED. WAKEFIELD.
WM. BOOTH.
JAS. ISAAC.
H LUCAS.
H MARTIN.
THOS. CANNON, Jr.

JOHN L. PHILLIPS, Secretary.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

THE eighth year of publication of the CANADIAN ARCHITECT AND BUILDER comes to a close with the present number. An index to the contents of this volume is presented herewith. At the commencement of a new volume and a new year, we may have a few words to say with regard to the progress achieved. Meanwhile, we heartily extend to every reader best wishes for a Happy and Prosperous New Year.

THE old Upper Canada College Buildings, Toronto, which it was proposed a year or two ago to use as a public museum and art gallery, are now occupied as a manufactory of tinware. "To what base uses do we come."

MONTREAL is to lose its distinction of having the largest bell on the continent of America. A Cincinnati foundry is about to cast what will be the largest swinging bell in the world for a church in that city. Its tongue will weigh 640 lbs.

THE Architectural Sketch Club, of Toronto, has been re-organized as the Toronto Sketch Club, and will, we trust, do much to encourage good work among its membership, which embraces the students in the various architects' offices in the city. The organization is informal in its character and is intended to cultivate the social as well as the professional element among its members. There will be competitions for designs and at each meeting a critic chosen from among the architects.

THE new Jamieson building at the north-west corner of Yonge and Queen Streets, Toronto, shows a rounded corner at the street junction, and serves to emphasize the great advantage which would have been secured by rounding in a like manner the corner of the new Simpson building. The opportunity is now past, so far as this building is concerned. Immediate action should be taken, however, to ensure, at least, the rounding of the north-east corner, on which stands at present an old and inferior building such as cannot much longer be allowed to occupy so valuable a site. While the opportunity of greatly improving the appearance of the city which existed by reason of the destruction of the former Simpson building has gone by, the importance of providing means of relieving the street traffic at this point should now be estimated at its proper value.

THE Art Student's League, of Toronto, is holding its annual exhibition at Roberts' gallery, on King street. There is some very creditable work on exhibition, showing that the League is doing good work. The exhibition is well worth a visit.

AN important step has been taken towards the building of the proposed bridge over the Hudson at New York. The general plans of the bridge have been approved by the War Department. The next step is the fixing of the exact location, when the detail plans can be completed, and then the projectors will be in a position to make their financial arrangements and go on with the construction of the bridge.

UP to 1st October buildings were erected or altered in New York this year to the number of 5,254, of which 86 cost $100,000 or over each. The total cost of these 86 buildings was $20,000,000. Of the entire number of buildings 2,067 were tenements or flats, and houses for residential purposes. New York seems to grow, but we fancy it will be some time before it ranks as the third city in the world as to size, notwithstanding the placing of it there by some of the United States journals.

M. L. WUARIN, a Frenchman who writes in the Revue Scientifique, on "Buildings in the United States," gives the latter nation much praise for the way they plan their houses and their household management. Among the things he commends are the interior drainage, free use of water, hygienic plumbing, heating (hot water heating), cooling methods, including the mechanical fan, distribution of hot water, laundry arrangements, methods of putting in coal, and last but not least, the district telegraph system. Old nations can sometimes learn a great deal from the new.

WE hear occasional complaints of the working of the lien law in Ontario, one being that a person who supplies building material may, by the collusion of the party who sells the land and the builder, be done out of his just rights. It is impossible to frame a law to meet every possible case, and if parties make up their minds to act dishonestly they can always find means to do so. We understand that since the lien law was amended in 1893 it has proved much more satisfactory than formerly.

A DEPUTATION of commercial travellers recently waited upon Hon. R. Harcourt, who has charge of the license branch in the Ontario government, and complained of the unsanitary conditions which prevail in country hotels, urging that steps should be taken to remedy this state of affairs, by the appointment of an inspector, or otherwise. Unfortunately there is good reason for the complaint, but the conditions referred to exist chiefly where there is no proper water supply or drainage system. It is probable the coming session will witness legislation to remove the cause of complaint.

A PROPOSAL to pull down the old court house in New Orleans, to make way for a more modern building, is meeting with much opposition, and justly so. The old building was the government house in the days of French and Spanish rule in America, and more history and romance cluster around it than perhaps any other building on the continent. If New Orleans wants a new court house let it be built on another site, and preserve the old building as a museum or art gallery, or something of that sort. There is too much of a tendency to remove the ancient landmarks. Boston is perhaps an exception to this rule.

THE Carmelite Monastery at Niagara Falls, Ont., is trying an experiment in heating by electricity, which will be watched with interest. The whole building will not be so heated, but having arranged for a fixed amount of power, all of which is not required for other purposes, the surplus is to be employed for heating. Electricity is not an economical agent for heating so far, and is used on street cars on account of its convenience, and because the current cuts no figure in the railway's expense account. But it will be employed at the monastery under favourable conditions, and the result will be of service in arriving at the relative cost as compared with other methods.

GREAT apprehension is felt lest the Church of England body in Toronto should lose St. Albans Cathedral, or rather the portion of it already built, the building and the land on which it stands being heavily mortgaged, without any money to meet the indebtedness. The hard times have, in common with many other institutions, seriously affected their revenue. Some time ago an appeal was made, but it met with a very small response, and now another request is made to save the property. A contribution of one dollar per member is asked for. It would be unfortunate if the building passed out of the hands of the church, as a large expenditure has already been made upon it.

WHILE it is unquestionably the duty of every architect to guard the financial interests of his clients, he should be equally careful to do justice also to the rights of contractors. Bitter complaints are sometimes heard of the manner in which architects, in the employ of wealthy clients, are accustomed to exact from their contractors an unnecessary amount of work, and put them to so much needless expense that on the completion of their contracts everything in the shape of profits is found to have been wiped out. In some cases the wealthy client instead of the contractor should have been called upon to pay the cost of the extra work required. We know of instances in which contractors, who faithfully tried to carry out their work in the best manner, became discouraged by the penuriousness and lack of consideration of the architects by whom they were employed. Such contractors are none too plentiful, and it is a pity that they should be forced into the belief that work skilfully and faithfully performed will bring no greater reward than if done in an inferior manner. We constantly hear comparisons made between the ancient skilled artisan and the artisan of to-day, and the desire expressed that it might be possible to obtain at the present time work equal in quality to that of former centuries. Yet how often does it happen that the skillful workman is put on a par with the inferior workman as regards the price which he shall receive for his work. If he is not willing to bring his price down to meet the tender of a man of inferior ability, in the majority of cases he loses the work. This is a poor method of encouraging a high standard of skill and honesty on the part of contractors, and we trust that this reference to the subject will cause architects who may have done injustice to contractors to extend to them a greater amount of consideration in the future.

THE purposes to which paper is now applied are almost numberless and cover every variety of industry. One of the most recent, in connection with the building trade, is for plastering. Two factories are in operation in the United States, one at Buffalo and one at Toledo, for the manufacture of paper plaster, and a third is about to go into operation at Fulton, West Virginia. About fifty men will be employed at the latter. The new plaster is practically fire proof, it can be put on in the coldest weather and will not crack, it is one fifth lighter than the old plaster and almost indestructible, and it can be used for roofing purposes also.

RATHER an odd suit came before Judge Morson at Toronto recently, in the Division Court. It will be remembered that Mrs. Dr. Oldright some time ago recovered $3,600 damages from the Grand Trunk, for injuries received by stepping into a hole at the new Union Station. At the trial Mr. Wm. Laidlaw, Q. C., who was her solicitor, used a plan of the station, which was produced by the G. T. R. and put in as an exhibit. The plan was made by Messrs. Strickland & Symons, architects for the G. T. R., and they now sue Mr. Laidlaw for $25, the price of the plan, saying that he ordered it. Mr. Laidlaw, on the other hand, alleges that the Grand Trunk had it made.

THE Southern Architect makes a strong plea for training the public taste in architecture and offers a suggestion as to how it can be done. The papers print a great deal of what is known as boiler-plate matter, that is, miscellaneous articles which are furnished in the form of stereotype plates, some of it good and some very inferior. The Architect suggests that articles should be prepared under the direction of the various associations of architects, stereotyped, and furnished to the papers at low cost, when they would no doubt gladly be published. It points out that at present architects are endeavoring to teach the public by an occasional artistic building, and that the process is very slow. It further advocates, by this means, the development of a style of architecture adapted to its own locality—the South which in time would grow into a renaissance. In the latter is there not a suggestion for Canada? Why not have a Canadian order of architecture? It would be of slow growth, it is true, but it will never come if a beginning is not made.

A DISTINGUISHING feature of modern house planning is the wide portiere entrance between apartments on the ground floor which apartments open into a square hall. Heating contractors complain that this kind of plan renders exceedingly difficult the proper heating of the house. It is claimed that if the radiating surface in a house of this description is evenly proportioned as between up and down stair apartments, the latter will be very inefficiently warmed, while the temperature of the former will be uncomfortably high. A heating contractor told the writer that he got over the difficulty by giving to the down stair apartments 75 per cent. more radiating surface than was called for by the rules of the heating authorities, and deducting in equal ratio from the up stair rooms. This arrangement is said to have worked satisfactorily. Presuming these statements to be substantially correct, it is clearly apparent that satisfactory results cannot be achieved by following any hard and fast rules on the subject, but that methods must be varied to fit the conditions.

THE ruinous competition amongst contractors in the smaller towns and villages is due in a great measure to the fact that workmen, when out of employment, become ready to snap at anything that gives promise of remuneration of any kind. Men who may be good mechanics in their several callings, but who know little or nothing of estimating, and less of the management of men or work, put in bids for contracts that are either away above the mark or ridiculously low. The former does little harm, as the overgrown tender is never considered, but the low tender injects its poison into the whole transaction, and leads the owner to believe that the legitimate tenders are much too high and that an attempt to take advantage is being made. This state of affairs generally ends in either awarding the contract to the incompetent low bidder or a second call for tenders. If the first, the contractor usually bungles the whole matter, partly from lack of knowledge and partly from the fact that he soon discovers there is no money in the job for him; then comes a series of schemes and efforts to slight the work and cram in inferior material, against which the architect or inspector "kicks," with the result that the contractor gets deeper and deeper in the mire, until at last, in despair, he either throws up the work or lowers his head to the inevitable, which is often ruin to himself and family. If new tenders are called for, the legitimate contractors, in their effort to keep out the "workman," will cut down their estimates to starvation rates, while the "incompetent" in his eagerness to get work, makes further reductions in his tender, thus dropping into the "trap" prepared for him by the regulars, and as a rule, his low figures catch the owner, in spite of the advice or protests of the architect, and the result is trouble and confusion all round, and oftentimes severe loss to the owner. This is a sad and injurious condition, but it exists in every town in Canada, and should be brought to an end. Can it be controlled? With proper management we think it can.

SHOULD ARCHITECTS BE LICENSED.

IT is probable the next session of the Ontario legislature will witness the passage of an act restricting the use of the title "Architect" to those who have taken a course of study and undergone an examination on the subjects comprised therein. Such a bill was introduced last session, but it did not reach its final stages before the house was prorogued. Some opposition was offered on the part of the Patrons, but when the matter was presented to them in its true light they withdrew their objections and agreed to allow it to pass. There seems to be nothing now it the way to prevent such a measure being placed on the statute book.

We do not know that there is any necessity for us to urge such a measure at length. The matter has already been fully discussed in our columns, and our views expressed. If it is necessary in the public interest to license medical men, who have to do with the lives of the people, and the legal profession, who have the welfare of their property in charge, why should it not also be required in the case of architects, upon whose work the safety of both life and property depends? It seems

strange that a surveyor, who lays out a piece of property upon which a building is to be erected, should have to undergo a course of training and pass an examination before he can do so, while the architect, who plans and superintends the erection of the building, the most valuable and important part of the property, involving considerations of comfort, safety and the pocket, may be a man utterly incompetent for the work which he undertakes to perform. The evil results of such incompetence is seen in a disaster like that of the collapse of the Ireland building in New York, which involved not only great destruction of property but the loss of fifteen lives.

But apart from this view of the matter, we should aim at improving our style of architecture. Why should our streets be lined with architectural monstrosities, when for the same money a building might be erected, which would be a thing of beauty and a joy forever? Architects should be artists as well as engineers and expert builders, and it is only by education that their tastes can be cultivated, and they become qualified to design buildings in which beauty may be combined with utility.

The great objection urged against a measure such as that referred to, and it has been brought against the medical and other similar licensing acts, is that it creates a close corporation, and that the examining and licensing body, composed necessarily of experts, is disposed to lay down such restrictions as to create a monoply for its own benefit. While we admit that there is some force in the objection, such an evil can be guarded against by having the rules for admission, and tariffs of charges, made subject to approval by the lieutenant-governor in council, or some other competent authority, who would see that all interests were properly guarded.

It is not the intention of the proposed act to interfere with the right of any person to plan his own building, or to employ anyone else, no matter who, to prepare his plans. It is proposed only to restrict the right of using the term "Architect" to those now practising, and to such persons as in the future shall take a proper course of study and undergo the prescribed examinations. Under the act of 1890, incorporating the Ontario Associations of Architects, the title "Registered Architect" is given to such as have or may qualify, but the distinction between "Architect" and "Registered Architect" is too fine for the general public to understand, and the provisions of the present law have, therefore, failed in their purpose, and the public have not received the protection which it was designed to give. The proposed act is, we consider, one which may well be enacted in the interests of the people.

A number of states in the American union are likely to pass similar measures. In New York such a bill was before the legislature at its last session, but did not pass. It will probably come up again at an early day, and Illinois and California, with no doubt others, will soon have such laws.

Mr. R. M. Fripp, architect, of Vancouver, recently gave a lecture on "Simplicity in Architecture."

Mr. A. C. Hutchison, the well known architect of Montreal, is announced to give a lecture on Rome, illustrated with stereopticon views, in St. James Square church, Toronto, on the 20th of December. Mr. Hutchison has recently returned from a trip to Europe, and his lecture will doubtless be full of interest.

ABOUT PAVING MATERIALS.

Although asphalt has come into pretty general use for street paving, there are some serious objections to it, and it is evident that we have yet to discover something which will be better adapted for street paving than anything now in use. Asphalt is expensive, and in damp weather, or a moist climate, is so slippery as to be unsafe. As a test on the latter point a record was kept by the city engineer of London, England, of the accidents arising from the condition of the streets, for fifty days, with the following result: Asphalt 1066; granite 719, wood 542. These figures indicate a serious objection to asphalt in such a climate as that of England.

The city of Halifax, Nova Scotia, has been making some experiments in paving materials for sidewalks, and the city engineer, in his report, recommends concrete on level streets, and asphalt for hills and less important streets. The cost of the former averaged $1.83 per square yard, while the latter cost only 70 cents, and under ordinary conditions could be put down for considerably less. The kind of asphalt pavement used is not specified, but from the low cost we infer that it is not such as would be suitable for roadways. This, however, by the way.

Wood block pavements have much to recommend them, but a great deal depends on the variety of wood and the way they are laid. Cedar blocks, so extensively introduced in Toronto and other cities in America some years ago, have not been a success. They will not stand heavy traffic and have been pronounced unsanitary. Hardwood is now being tried, and the Timber Trades Journal declares that in the near future the whole of London will be surfaced with wood. The variety now being used is the Australian jarrah, which has been tested in the metropolis, on some of the Paris boulevards, and in some of the provincial towns, in every case with satisfactory results. It has supplanted everything except Baltic fir, and is gradually but surely displacing that. If blocks four inches deep will answer, and they are now being tried, it will bring the cost down almost to that of Baltic fir, which has to be laid six inches thick.

Jarrah is the hardest and most durable of all Australian woods, and it is stated it will resist the wear and tear of London street traffic as long as granite. It is free from knots and does not shrink to any appreciable degree, the grain is close and tenacious, and it resists the influence of damp and moisture, in fact, being of the eucalyptus family, it is a valuable antiseptic, rendering it valuable from a sanitary point of view. It affords a good foothold for horses without being slippery. What more need be said in its favor?

Other Australian hardwoods are being tried in Great Britain, one known as karri being apparently second only to jarrah, and Tasmanian blue-gum is to be tested in Glasgow. It is, of course, too much to expect that any of these foreign woods will come into use in Canada, where we have so much wood of our own. Vitrified brick, if it can be brought down to a reasonable price, will probably be the pavement of the future in Canadian and American cities. Trap rock, referred to by us in the November number, may supplant the ordinary macadam for boulevards and park drives, but it would probably be too dusty for business streets and could hardly withstand heavy traffic.

One of the most unlikely paving materials which has been introduced anywhere is described in the Manufacturers' Record. At Norfolk, Virginia, a plant has been set in operation for making paving blocks out of the grass which grows on salt water marshes. The grass is subjected to heavy pressure, which forms it into large blocks, which are cut by circular saws into smaller blocks, 5½ inches thick, provided with strong wires, which run lengthwise. These blocks are then subjected to a bath in three tanks of different kinds of oil, which renders the fibre supple. A pavement of this material has been tested for over a year in Philadelphia, on one of the busiest streets near the stockyards, and with satisfactory results. It is smooth, noiseless, and horses cannot slip on it. Large contracts for these blocks are said to have been secured from New York and Pittsburg. We must, however, class ourselves as doubters as to the wearing qualities of such a material, without further information.

But our readers will perhaps smile with incredulity when we mention another material for paving, which, if such a reputable journal as the Literary Digest is to be believed, has been successfully tested. In the southern states, where sugar manufacturing is carried on, there are millions of gallons of molasses produced, which, after supplying the market, remain over and become a waste product. The head chemist of a refinery at Chino, California, Mr. E. Turke, was led to make an experiment with this molasses, and had a walk one thousand feet long made between the factory and the main street, mixing sand with the molasses and putting it down in the same manner as asphalt. It dried quickly, became hard and remained so, the sun making it harder instead of softening it. A block of the composition two feet long and one foot wide was subjected to severe tests, being laid with its ends resting only an inch or two at each end on supports. When struck in the middle with a heavy hammer it showed no sign of cracking or bending. Notwithstanding this test, we can hardly imagine molasses coming into general use as a paving material.

It is clear from what we have stated that we have not yet passed the experimental stage in the matter of pavements.

ILLUSTRATIONS.

RESIDENCE, BISHOP STREET, MONTREAL, FOR DR. D. F. GURD—ROBERT FINDLAY, ARCHITECT.

FACTORY BUILDING FOR THE METALLIC ROOFING CO., TORONTO—HENRY SIMPSON, ARCHITECT.

PROPOSED BUSINESS PREMISES, VANCOUVER, B. C.—R. MACKAY FRIPP, F.R.I.B.A., ARCHITECT.

TOWN HALL, CARLETON PLACE, ONT.—G. W. KING, ARCHITECT, TORONTO.

The town of Carleton Place, Ont., is to have a town and fire hall, which will be erected on Bridge street, the main business street of the town, at the south end of the iron bridge across the Mississippi river. The size of the building will be 61.6 x 104 ft., without projections. The north-west corner is cut off by the river, making the Bridge street frontage only 52 feet.

The material will be limestone, in random rubble masonry, with Beckwith freestone trimmings, slate roof and galvanized iron cornices. The wall fronting on the river will be concrete to ordinary water line, dimension stone in cement to one foot abve high water mark, which is the underside of the basement floor. The floors will be of slow burning construction, metal ceilings throughout, divided into panels by wood mouldings. Basement will contain caretaker's rooms with separate entrance, cells for male and female prisoners, with separate staircase to court room and entrance. Also pump room, boiler room, furnace and coal room. On the ground floor is clerk's office, with vault, having outside light, mayor's room, committee rooms, council and court room combined, public library with reading and smoking rooms, separate entrance to hall staircase and ticket office. In rear is an engine house 26x65 inside, with Mezzanine flat under stage containing firemens' recreation room, gymnasium, and lavatory with shower bath. On the first floor will be the public hall, seating 800, with gallery seating 250, stage 31x65, fitted with the latest improvements and nearly equal in equipment to a regular theatre stage. All principal rooms will be finished in oak, the others in pine. It will be steam heated, with electric bells and electric light. Cost, including river foundations, $25,000. M. Ryan, of Smith's Falls, is the contractor.

THE NEW GLOBE BUILDING.

A printing office is generally considered a hazardous fire risk, but the new Globe building in Toronto, to replace that destroyed by fire last January, now rapidly approaching completion, will be fire resisitng. It stands on the corner of Yonge and Melinda streets, upon the same site and occupying precisely the same space as the old building, but is very much more substantial. It is of skeleton construction, similar to the new Simpson building further up the same street, but all the columns are built into the brick walls, and the floor beams are encased in concrete. The interior is finished in plaster instead of metal sheeting as before. The interior arrangements are much the same as in the old building, the only feature of essential difference which will strike onn on entering being an iron stair-case in the business office leading to the upper storeys. Some of the mechanical departments, however, such as the stereotyping room, will be shut off so as to prevent the spread of fire, should one break out. Only the Yonge street end is designed to be fire proof, the part ftonting on Jordan street, which is cut off by a lane arched overhead, and which will be rented, being of ordinary construction. The building is so planned that two additional storeys may be added in the future. It will be one of the most convenient and best equipped newspaper offices on the continent: Burke & Horwood are the architects.

A HAMILTON BOY'S SUCCESS.

Archie Rigg, a Hamilton boy and resident of that city up to a short time ago, has made himself prominent in St. Louis in recent architectural competitions. He prepared plans for five competitions and was successful in winning one first and one second, while dozens of the leading architects of St. Louis failed to get a place. His plans for a $25,000 residence were considered the best and were accepted, winning for him the cash prize of $100, in addition to which the firm he is with gets the superintendence of the work. In a competition for an $85,000 office building he won second prize, capturing the St. Louis Competition Club's bronze medal. J. L. D. McCarthy, architect, and F. J. W. Hirst, engineer, as chairman and secretary of the Competition Club, write saying that Rigg's work cannot be given too great praise. As Archie is but a boy yet, a brilliant future seems to be in store for him.

DEFECTS OF THE ONTARIO LIEN LAW.

In pursuance of a conversation which the writer had recently with a well-known dealer in builders' materials at Toronto, the latter has contributed from his own experience the following facts relative to the inadequate protection afforded the material dealer by the present Lien Laws of Ontario :

A contractor two and a half years ago came to me and requested materials for building four houses on Charles street, Toronto. He stated that he had purchased the property from the Westminster Presbyterian church authorities, and had secured through a firm of lawyers a loan sufficient to complete the buildings, and that the mortgage was completed and he would be able to pay me within thirty days after delivery. Enquiry of the proper parties showed the contractor's statements to be substantially correct. About the time when payment should have been made me, the contractor came to see me and said that he had just had differences with the lawyers and that he had recalled his mortgage as the lawyers refused to give him the amount of money he was entitled to. To protect myself as regards filing a lien and also with the view of not hindering the contractor from getting a loan, I continued to supply him with material for six months longer. He was not successful, however, in getting his loan, and I filed my lien, which in due course was established.

Another period elapsed, and then the mortgagees of the land called upon the church people to pay off the mortgage. The church people requested the mortgagees to sell the property, and the same was offered for sale but not sold. This action was undoubtedly taken to freeze out the liens on the property, and which I understand legally was done. About two months after the sale, certain parties connected with the church suggested that as I was the principal lien holder, my claim amounting to about $600 for simply materials supplied that I should take the property over and complete the fresh pair of houses, which were partly built.

I considered the matter, and spent considerable time in arranging matters, and then made the church people an offer, and the church committee appointed three of their number to confer with me and to report at their next meeting. The interview took place and was satisfactory to two of the sub-committee, but the third member of said committee opposed the acceptance of my offer, and carried his point, with the result that he with others on the committee took hold of the property, completed two of the houses, never offered in any way to recompense me for all my materials supplied in good faith, and as far as I know, the church is reaping the benefit of the advantage afforded them by the law of grabbing everything in sight.

Another case is that of a contractor who bought a piece of property, and stated at the time of ordering material from me that the loan had been arranged, gave me the name of the lender, whom I found to be a monied man and who informed me that he intended to loan the money. When the goods had been delivered and the first payment should have been made, the lender backed down. It was only then that I discovered that there was an agreement referred to in the Registry office between the original owner of the land and the contractor. This agreement at first was not to be found, but afterwards through my promising to assist in trying to obtain a loan, it turned up. It then appeared that under this agreement if the contractor did not pay down the whole of the purchase money within a short period that he forfeited all interest in the property. My lien was registered and carried into court, and I closed the case. The original owner of the land stepped in, completed the houses, and the labourers and material men lost everything.

In another case a contractor bought material from me to the amount of $700 on the strength of the statement that his mortgage was arranged. At the time he gave me his contract for stone, he promised me the contract for bricks, lumber, lime and cement. I confirmed the stone contract by letter the next day, some days later secured the brick contract and confirmed this by letter, and later on I also secured the lumber contract.

No money was forthcoming when promised and to protect myself I filed a lien. The case came up at Osgoode Hall, and then it became known that a well-known gentleman of Toronto was at the contractor's back, and much to my surprise the defence was that as the contracts were made at different times it was not a general contract, and that I was only entitled to about $5 for a load of lime delivered within the statutory time for filing liens. The case was adjourned to allow us time to bring witnesses, and as the contractor appeared to be completely under the thumb of his backer, I considered it necessary, notwithstanding he was defendant to the suit, to subpoena him, lest he might not be on hand when the case was called. I personally went with the serving party to the contractor's house. At the interview in the presence of the third party, the contractor, (I believe thoughtlessly) corroborated my convictions that it was a general contract and not individual ones. I then had to arrange, at his wish, to keep him clear of his backer until the case was called, and which I did. The case was called and the solicitor for the gentleman at the back of the contractor called his nominal client (the contractor) as a witness. The latter, much to his backer's surprise, confirmed my statements. After this, the decision of the court was given in my favor. On appeal it was given against me. On further appeal the case was going decidedly in my favor when the contractor's backer compromised in court by paying me $475. The contractor agreeing in the sweet bye and bye to pay me the balance, which balance has not so far materialized.

PERSONAL.

Mr. H. W. Worrall, architect, has opened an office at New Westminster, B.C.

Mr. Thomas Webber, one of five brothers in business as contractors in Hamilton, is dead.

John Strickland, the well-known builder and contractor, of Brantford, is dead, aged 63 years. It was he who built the asylum for the blind at Brantford.

The "New Books" department of the December Review of Reviews is crowded by the holiday publications, but contains brief reviews of the best literature of the season. The department is fully illustrated.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The series of monthly dinners and course of lectures for the winter were inaugurated on the 10th December. A number of the members dined together at the St. Lawrence Hall and afterwards adjourned to the rooms of the Association, New York Life Building, when a lecture was given by the president, Mr. A. C. Hutchison, on "Ancient Rome," illustrated by a large number of excellent lime light views. The lecturer began by making an analysis of the history of Rome, and fully explained each view as it passed on the curtain in a clear and interesting manner. Mr. Hutchison having passed the greater part of last winter in Italy and Sicily studying the ancient monuments, proved to his audience, who thoroughly enjoyed his lecture, to be very well acquainted with his subject. Mr. A. T. Taylor, vice-president, was in the chair, and there was a good attendance of members and students. On motion of Mr. J. Venne, seconded by Mr. Theo. Daoust, a vote of thanks was accorded the lecturer for his paper.

Future gatherings have been arranged for the second Tuesday of the month during this season, with the following program : Jan. 14, Mr. R. Findlay, "Old Colonial Architecture" (with illustrations); March 10th, Mr. J. Venne, "The Making of Plans for a Building" (with illustrations); April 14th, Mr. W. E. Doran, "Truth in Architecture." The February meeting has not yet been definitely arranged for.

The following examiners have been appointed for the examinations to be held during the coming year : For Montreal, Messrs. A. C. Hutchison, A. T. Taylor and J. Venne ; for Quebec, Messrs. J. F. Peachy, H. Staveley and C. Baillairgé. Examinations will take place this winter in Quebec for admission to study and registration on the 29th, 30th and 31st January. One month's notice is required to be given the secretary by intending candidates.

The Association has petitioned the Attorney-General for the repeal of the law known as the Augér Bill, and for substituting for it the law which was in force before the Augér law was known ; or that in default of its repeal, that the following amendments be made to it : 1st. That the rights of the lenders remain privileged and free of all proceedings which would tend to delay their recovering the amount of their loan. 2nd. That no discrimination be made in this law for anybody except for the laborer. 3rd. That the time when a building can be legally termed completed be clearly defined.

The proposed building by-laws which were prepared in English by a committee composed of members of the Association appointed by the Council at the request of the municipal authorities, have been translated into French by the latter and returned to the Association for comparison and further revision, which has just been completed. It is hoped that this by-law will be passed without amendment at an early date, as the remedy is greatly needed, and Montreal could then be classed among the best governed cities as regards the erection of its buildings.

A PROTEST.

TORONTO, Dec. 3rd, 1895.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR : Will you kindly favor me with space in your paper to cite a prevailing grievance, which is as time advances becoming more and more pronounced. It is the practice of government employees, with a permanent salary, to compete against architects who have only their profession. Men holding positions in the government service are frequently employed as architects by some of our largest corporations, and others.

Now is this fair, is this just to the architect, the government and the public? I and others think not, and know that if the matter was brought to the notice of the Minister of Public Works he would not countenance it, for if I am correctly informed, employees of the Department are not at liberty to carry on a private business. It is in reason that such should be the case, for it is impossible for any one man to attend to two separate businesses at the same time, and it is self-evident that a man carrying on a personal business cannot keep his mind from dwelling on it at all times, which would in this case interfere with the successful discharge of the government business. It is not improbable that during some part of the day he will require to be on the works to give a decision on a critical point of construction which is not understood by the contractor. This cannot wait until he is liberated from business ; when and where is it done if not on the works, directly after it is discovered? It is also a known fact that plans prepared by one of these men have been figured on by contractors in the government office. Their methods of getting patronage are not just to the profession to which they imagine they have a right to belong. They make capital of the fact that they do it after hours, have no office expenses, and must have constructional ability or they could not hold their present situations. I have never heard what claim they make to be designers ; they are wise if they do not lay stress on that.

These methods of doing business are highly detrimental to the profession, to say nothing of the effect on the character of the men who resort to them. I cannot longer withhold my protest at seeing the profession pulled down from its hitherto high standard as the highest and noblest art in the universe, by such men, for a mere monetary consideration, for I have no doubt that if they could not add to their munificent salaries they would not do the work at all. If they would even have the decency to maintain the recognized schedule of professional charges, it would place us on an equal footing in an unequal race. Then the public would probably give their commissions to architects who could devote their whole time to their client's interests, which would necessarily mean architects whose time is their own.

Very truly yours,

CONN.

TORONTO SKETCH CLUB.

A meeting was held in the office of Messrs. Darling, Sproatt & Pearson, on Tuesday evening, Nov. 19, when a Sketch Club was organized for the purpose of studying design. This club differs from the old architectural clubs to a great extent. In the preceding clubs, lectures, classes, etc., were of the first importance, while design was considered a secondary matter. The relative merits of classes for lectures and design were fully discussed at this meeting and it was resolved that design was the most necessary function of an architect and more attention should be paid to this subject than is usually taken by students. The study of construction can be carried on privately as books give all the information necessary to make an architect expert in that line. With design it is different. A design may be prepared at home, but it is absolutely necessary, if the student is to advance, that his design be criticized by some one competent to do so. A designing club of some kind is, therefore, what a student should attend, so that the faults or merits of his design may be pointed out. It was decided to have the meetings as informal as possible and any point about a design openly discussed. In order to obviate the expense of running the Club, it was decided to hold the meetings in the offices of the numerous architects who would favor the Club in this particular. The architect at whose office the meeting is held will act as critic on the occasion. After the criticism is over, the members cast ballots for the designs they consider entitled to 1st and 2nd place.

The first regular meeting was held in the office of Messrs. Strickland & Symons. Mr. Symons acted as critic. The subject was "An Entrance." It is the intention to have the subject only chosen and the members design in any style they wish.

A meeting was held at the office of Mr. E. B. Jarvis, on the evening of the 19th inst. The subject on that occasion was "A Gable." The next meeting will be held in the offices of Messrs. Darling, Sproatt & Pearson, when Mr. Darling will act as critic. Reports of these and all subsequent meetings will appear in the CANADIAN ARCHITECT AND BUILDER. It is also the intention to publish such of the sketches as shall possess sufficient merit for that purpose.

THE FORESTERS' TEMPLE.

Some time ago we published an illustration of the temple being erected on the corner of Richmond and Bay streets, Toronto, for the Independent Order of Foresters. The charter of that organization authorizes them to hold real estate only to the value of $100,000, whereas the building, including the site, is expected to cost about $260,000. It has just come out how this provision has been avoided. Oronhyatekha, the supreme head of the order, has an amanuensis named Jessie Brayley, and this lady suddenly finds herself possessed of considerable wealth (on paper), the property above referred to being in her name. The site was deeded to her, and she gives mortgages to the trustees covering the value of the property. By this means the limitation imposed on the Order is avoided. The registration of the papers gave publicity to the facts.

CORRESPONDENCE.

[Letters are invited to this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

FIRE PROOF MATERIALS.

MONTREAL, December 3rd, 1895.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—I beg leave to question your views on fire proofing. Judging by several articles which have at different times appeared in the CANADIAN ARCHITECT AND BUILDER advocating the use of concretes for fire proofing, I think you have overestimated the value of that material for that purpose, and I consider that the letter signed "An Architect" is to the point and ought to appeal to the unbiased judgment of anyone having only public interest in view.

That concrete business is as old as the hills and has been pushed for all it is worth in every imaginable shape, and up to this day there is not a single instance where its most sanguine advocates have been able to prove its superiority over porous terra cotta. There is one thing we all know, and that is that at the Denver tests it was shown conclusively that porous terra cotta was the only material that stood all the tests. We all know that porous terra cotta is absolutely fire proof and that we have never heard of a building fire-proofed with porous terra cotta ever having been destroyed by fire. Does it not then stand to reason that it is safer to use a material that we know is fire proof, rather than run the risk of adopting what we only consider as good, but of which we only have opinions and no positive facts? Is it not better to leave well enough alone?

Yours truly,

N. T. GAGNON.

[NOTE.—Mr. Gagnon is mistaken in saying that we advocated the use of concrete for fire proofing. We only gave the facts as they were presented to us, and did not express an opinion of our own as to the relative merits of concrete and terra cotta.—EDITOR C. A. & B.]

SAFETY OF HOT WATER HEATING SYSTEMS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The prevalence of accidents to hot water heating systems at this season of the year entitles practical engineers to enquire into cause and effect.

This system of heating is annually becoming more generally used both in public buildings and private dwellings, and the amount of ignorance displayed as to the requirements of safety is remarkable. When we consider that nearly every plumber has developed into a "practical steamfitter" (so-called), who will undertake the erection of the most intricate systems of heating apparatus, and considers himself fully competent of doing so as soon as he is able to run a straight thread and cut a piece of pipe—notwithstanding that the theory of expansion and contraction is an almost unknown thing to him. When we examine some of the arrangements laid out by these men we wonder that some of the explosions ("break-downs" they call them) that have followed their experiments have not resulted in a serious loss of life. Thus, so far, Dame Fortune seems to have been kind to them in this respect.

A very large number of business blocks are now heated by this system, and the usual class of labor employed is a fireman who has not the slightest knowledge regarding the nature of the plant under his charge. It is therefore especially necessary that all systems should be properly examined before being passed over to this class of help.

It has been my lot to have to look into several more or less serious "break-downs" of hot water furnaces, to ascertain the cause, and in every case the cause of the whole trouble was traced to want of expansion. One instance will suffice. A pair of twin boilers blew up some time ago in a manufactory here, and made things exceedingly interesting around the establishment. The boilers were set side by side and were so arranged that either one or both boilers could be used for the whole system as occasion demanded. Boilers were attached to separate headers as shown in diagram. For convenience we will discuss arrangement of pipes under separate heads. For the information of any of your readers who are not well versed in this method of heating, I wish to point out that the whole efficiency of the system depends on a proper and systematic arrangement of mains and their accessories.

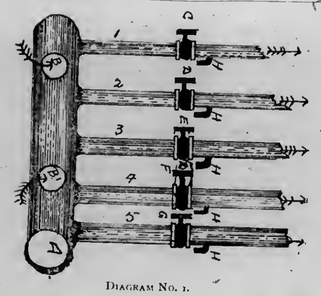

DIAGRAM NO. 1.

Diagram No. 1 represents "flow" header, designated A, fed from boilers at B, B' mains shown at 1, 2, 3, 4, 5, distributing hot water to several radiators throughout the building.

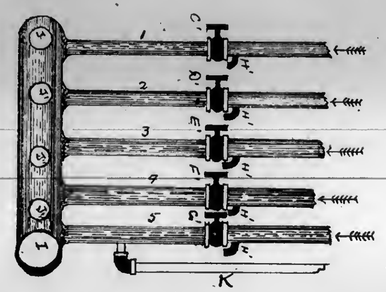

DIAGRAM NO. 2.

Diagram No. 2 represents return header, designated I, return from header to boiler being effected at pipe J, J', J'', J''',—pipes from the radiators being arranged as 1, 2, 3, 4, 5.

Boilers were each provided with shut-off valves between header and boiler on each pipe. As water is heated it flows in direction indicated by arrows. My object, however, is not to discuss action and circulation of water so much as arrangement of mains, etc.

By diagrams it will be noticed that each line of main is provided with valves, as at C, C', D, D', E, E', F, F', G, G', and drip valves as at H, H', thus enabling any particular line of main to be operated singly or in conjunction—a very well arranged system and an arrangement that will recommend itself to any engineer for various reasons: (1) Because either one or both boilers can be used; (2) because any one line of main can be used; (3) Because in case of accident occurring to one of the boilers or any radiator, repairs can be effected without disabling the whole system; all of which tends to show that the person who laid the arrangement of pipes and mains had given some thought to economy and efficiency.

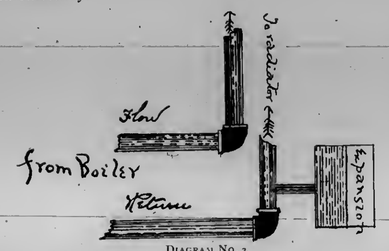

DIAGRAM NO. 3.

By referring, however, to diagram No. 3, we find what may almost be called a fatal error. This diagram represents arrangements made for expansion. Main 5, 5, leads to a small set of radiators in upper storey of building, and expansion tank had of necessity to be higher than this. The reader will observe that expansion is taken from the highest point on return main 5. By tracing out main 5 in diagrams 1 and 2, it will be noticed that these mains are each provided with valves and drips the same as the others, plainly signifying that they were intended for same purpose. Practical engineers can easily imagine what would happen in case these valves were closed; there would be a gradual expansion and increase in pressure until strength of material had been reached, and then! Well, an enquiry if not an inquest.

Just what happened in the case in question was this: The weather was mild and main B was not required; a good fire was built under the boilers, resulting shortly after in a wreck, and the enquiry, "How did it happen?" etc.

In this as in many other cases the steamfitter seems to have had a fairly good idea of how to lay out and run mains, but no idea whatever as to what was required to prevent disaster by over pressure, and consequently the whole of his good work was negatived by want of knowledge on this point.

In diagram 2, attached to return main 5 is shown a small pipe in outline. To prevent possibility of accident through any of the valves in the mains being closed, this should be continued to expansion tank in upper storey. And in addition to this, each of the boilers in question should have been provided with a safety valve, set for required pressure, as an extra precaution. There is not the slightest doubt but that this class of boiler is just as liable to explosion as any steam boiler, and the sooner architects and others realize this fact, the better will be the reputation of this class of heating.

Yours truly,

ENGINEER.

A portion of the geological museum building at Ottawa has been declared unsafe and the specimens have been removed from it. A new building for the museum and a new custom house are said to be in prospect.

LONDON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

MR. PEELE, stone carver, has started a private school for the teaching of architectural and model drawing.

Herbert Matthews, architect, will move into new offices in the Albion block at Christmas.

The erection of the G. T. R. car shops will increase the population and give an impetus to the building trade. There is scarcely an empty house in the city at present.

Many of the large buildings that have gone up this year are not yet completed, the Y. M. C. A. being one of them. London has now some of the finest public buildings in the country.

The London Waterworks Commissioners control the water supply, and have been running the plant so economically that they were enabled to turn over more than $20,000 to the city. They own about 250 acres at Springbank, where the waterworks plant is situated, and the value of the property has been enhanced by the advantages it possesses of having fine sites for summer cottages, as the electric street railway will run down there next summer.

HAMILTON ART SCHOOL.

THE directors of the Hamilton Art School have been considering a scheme of the principal, Mr. Ireland, by which the work of the classes may be rendered more efficient, and the students encouraged, after they have completed their elementary course of instruction, to keep in touch with the school. With these objects in view it was resolved at a late meeting

(1) That any student, male or female, who has paid fees for the full term of three years, may attend the evening classes free, by becoming an annual member, which will cost only $1 a year. By granting this liberal concession it is expected that students will avail themselves of the three years' course more generally than has been the case in the past, instead of from two to two and a half years on the average only, and thereby avail themselves of a life-long privilege. Hitherto students, after leaving the school, have not cared to trespass on Mr. Ireland's time for some occasional help which they needed, and did not feel disposed to pay a year's fees for the same. In the future they will be able to get this, as an ex-student member's privilege.

(2) That students attending the all-day classes may attend the Tuesday and Friday evening classes free.

(3) That pupils over 14 years of age who are attending the Saturday morning classes be also allowed to attend the Tuesday and Friday evening classes free.

(4) The rule that students must join the school either at the commencement of the term or half term is amended; they can now pay fees in advance for the unexpired portion of a term.

The extent to which a chimney can poison the atmosphere has been scientifically determined by a test made in Berlin. The soot which comes out of the chimney of a single sugar refinery was gathered for six days and was found to weigh 6,800 pounds.

Some years ago the old Nova Scotia Penitentiary was sold to the Church of England Building Committee. It was proposed to use the stone for a new cathedral, but the project fell through. The building has now been sold to the People's Heat & Light Co., to be used for gas works. It cost the committee $10,000 and they sold it for $22,000.

The specifications of the engineers' department of Toronto contain a provision to distribute moneys due to defaulting contractors among persons who supply material, after the claims of workmen have been paid in full. As the provisions might be taken advantage of for the purpose of filing fictitious claims, the advisability of eliminating it altogether is being considered.

A deputation of the Toronto Builders' Exchange appeared before the Water Rates' sub-committee of the Executive to complain of a clause compelling the payment in advance of a charge for water of 5 cents a thousand on brick, 2½ cents a toise on stone, and 2¼ cents a barrel on lime. It was also urged that such charges were unfair, and that the charge should be made on lime alone. Ald. McMurrich, chairman of the committee, suggested that it would be a move in the interests of the city if builders were permitted to use the city water free for building purposes. The revenue, as shown by the Treasurer's statement, was small, and under almost any system the honest man would pay and the dishonest man would not. The suggestion of th chairman was adopted.

STUDENTS' DEPARTMENT.

C. A. AND B. COMPETITION.

THE Judges in the CANADIAN ARCHITECT AND BUILDER'S competition for a City Store Front have carefully examined each of the designs submitted, and have made their report thereon, as follows:

"This draughtman's competition is very much in advance of the average—all the designs submitted having some points of merit—making it rather more difficult than usual to make a selection. As usual there is strong evidence of the tendency to sacrifice the study of the planning and construction in favor of a pretty elevation. In view of this, it is not surprising that we should have awarded the first position to one who has certainly a commonplace elevation, but the best all round grasp of the situation.

The first three places have been awarded to: 1st, "Romanesque;" 2nd, "Penny;" 3rd, "Arrius."

"Romanesque" shows the proper spirit in which to enter such a competition as this. In the style chosen, whatever opinion may be in regard to a style which has for one of its main characteristics the use of small openings in large wall space, the author has handled it well, though the proportion of storeys is not good, the upper storeys being too high for the ground floor, which makes the scale of the latter detail too fine in proportion. The plan shows very little accommodation on either floor for such an expensive building, though the parts are well arranged, with the exception of elevator and entrance. The small area at back has hardly sufficient light for a main office.

In "Penny's" design the general grouping of storeys, with the exception of excessive height of ground floor, is good; the proportion of voids and solids is satisfactory; the main cornice is not well studied. His arrangement of plans shows insufficient lighting of ground and upper storeys. The planning of office flat for such a large building gives too small a number and an unsatisfactory arrangement of offices. The elevator and stair arrangements on ground floor are extravagant. The stone piers each side of shop window are rather small to carry weight above, and no other construction is shown either for carrying front or floors of building.

"Arrius," like "Romanesque," shows a good grasp of the situation. The elevation up to main cornice, with the exception of archevolt over shop wiudow, is good. The storey over main cornice is too high in effect. The window in gable suggests a pitched roof. The value of the design of gable depends entirely on how the roof is to be constructed, which he has in no way indicated. His plan shows good construction. The light is deficient and entrance hall not very good.

"Grad." He has spent too much time on his iron construction, which could not be taken into consideration, though carefully shown. His elevation is good, but he has sacrificed the lighting of his top office to exterior effect. His office plan is not well arranged. It would have been better to arrange his office vaults over ground floor vaults. No private stair to basement is shown. He deserves great credit for his construction all through.

"Bon-ton" has one of the best elevations sent in. His office entrance is good, but a little extravagant. The position of vault spoils an otherwise well planned store. His office arrangements are fairly good.

"Wreath" has a good plan, though bad entrance to office—2 ft., 6 in.—hardly wide enough for main stairs. His elevation is too affected. Such a mass of masonry over his shop window is not good. His first floor windows are altogether too small.

"Erectheus" has placed himself out of the competition by his style of rendering, which does not conform to conditions. He shows no plan or construction.

"Bluenose"—Plan too small, though not bad. Elevation not badly grouped; rather commonplace.

"Boreas"—Store too small; vault badly placed; side entrance too wide; shop front too small; office plan too much passage; rooms too small. This elevation shows a feeling of English Renaissance, though unstudied in detail and indicating lack of knowledge.

"Doric" wants a little more study.

EDEN SMITH.
FRANK WICKSON.
J. GEMMELL.

[The names of the successful competitors are: 1. "Romanesque," (Mr. Melville P. White), Toronto; 2. "Penny," (Mr. Charles P. Band), Toronto; 3. "Arrius," (Mr. Elmer H. Russell), Toronto. The successful designs will be published in the New Year number of the CANADIAN ARCHITECT AND BUILDER.—THE EDITOR.]

MATHEMATICS AND CONSTRUCTION IN THE ECOLE DES BEAUX ARTS.*

THE reputation of the architectural department of the Ecole des Beaux-Arts of Paris is based almost wholly on its strength in design. The curriculum, however, necessarily includes a fairly thorough course in mathematics and construction, because graduates of the school are granted diplomas permitting them to practice architecture. Nominally they are also required to have had two years of office practice, but in reality a few weeks suffice.

The students are divided into two classes, known as first and second, and to pass from the second to the first fifteen "mentions" are necessary. They are one each in mathematics, descriptive geometry, stereotomy, construction, perspective, modelling and archeology, two in drawing and six in architecture. A bright student will accomplish this work in about two years, but it is possible for one who enters in March to do it in sixteen months. The first five mentions, which represent rather more than half the work, are the subject of this paper.

The instruction is given entirely by lectures, which are an hour in length, and usually come no oftener than twice a week on any subject. A French lecturer includes much more in a lecture than do our professors, and the result is that the subject is less thoroughly grasped by the pupil. It is hoped that the reader will be able to form some conception from the number of lectures in a course, and from the problems and drawings required during it and on examination, of how carefully the ground is covered. The examinations will serve as the best criterion of the thoroughness attained. Merely outlines of the problems are given, and without the details the reader will be apt to conceive them as simpler than they really are.

Of course, any wording offers considerable opportunity for different interpretations of the amount of work expected, but there is such a spirit of competition pervading the school that the fullest interpretation usually results. In forming an opinion of the course the reader must bear in mind that all subjects are taught from the standpoint of their application to the study or practice of architecture, and everything not having a direct bearing on the subject has been eliminated from the curriculum.

The examinations are oral, but are supplemented by problems worked en loge, which means that the student is assigned to an alcove and required to work out a problem in a specified time, varying usually from six to twelve hours.

The course in mathematics comprises about thirty-six lectures, and includes the subjects of algebra, trigonometry, conic sections, analytical geometry and mechanics. The algebra includes equations as far as the solution by successive approximations of numerical equations of the third degree, decreasing geometrical progression, logarithms and interest.

Trigonometry includes the solution of plane triangles in general, the calculation of triangles by logarithms and the relation between a plane in space and its projection.

Conic sections receive much more attention than the two preceding branches. Quite a careful study is made of the curves, resulting from the intersection of the cone and cylinder by a plane, and of practical methods of drawing them and tangents to them; also of methods of measuring surfaces and volumes frequently met with in construction.

Analytical geometry is only touched upon, and is taught mainly for its application to the curves of flexure of beams. It includes the curves of the second degree except the hyperbola, equations of the line and circle referred to polar co-ordinates and in geometry in space, the equation of the line and plane and the angle between two planes.

Mechanics includes only statics and simple machines. Under the first are considered parallel and concurrent forces, composition of forces, parallelogram of forces, couples, moments, general equations for equilibrium, centres of gravity and resolution of forces; under the second, the lever, balance, pulley, tackle, windlass, gears, inclined planes, the wedge, screw and various applications.

The examination on this course in mathematics and mechanics is both written and oral. The written one usually consists of two questions, one of which is almost always the solution of a triangle and the other on mechanics. The oral is about three questions chosen at random.

As a course in mathematics it is certainly very incomplete; whether as a course specially designed for students of architecture it is also incomplete is a subject affording ample opportunity for discussion. Enough is included to suffice for the courses which are to follow, and the deficiency seems to be more in drill than in subject matter. Though the French seem to have found it sufficient to answer the actual needs of an architect, the American practice of adding a little more for the sake of the mental drill is a most excellent one.

*A paper by James M. White, Assistant Professor of Architecture in the University of Illinois, published in the Technograph.

In contrast with it is the course in descriptive geometry, which is very thorough, being the principal basis of stereotomy and perspective. The course includes fifty or sixty lectures, of which about ten are a review of the part required for entrance and ten on the finding of the most common shadows.

The best conception of the course is to be obtained from the examination questions, a list of which, divided into six series, is furnished to the students. The oral examination, part of which comes at the middle of the course, is on questions from the list, one being chosen at random from each series. The first series contains about twenty-five questions on the line and plane; the second, thirty on the sphere, cone and cylinder of revolution, problems of angles, the solution of trihedral angles and regular polyhedrons; the third, thirty on cones, cylinders, pyramids and prisms; the fourth, twenty-two questions on surfaces of revolution; the fifth, twenty-five on ruled and helicoidal surfaces, and the sixth, twenty-five on shadows.

Twenty-two plates of about forty of these problems must be drawn, and constitute part of the examination. The problems on the first six plates are to be chosen from the first two series, on the second six plates from series three, four and five, and the remaining ten on shadows.

One problem must be drawn en loge, for which six hours is allowed. The problem given last year was: A cube stands with its diagonal vertical; a second cube of the same size has its diagonal coinciding with the first, but is turned through an angle of 22½ degrees. Draw in plan and elevation the intersecting cubes, and find the shadows at 45 degrees on the solid and on the plane of projection. Pillet's text-book on "Descriptive Geometry" is closely followed in the lectures.

The course in stereotomy is also a thorough one, and includes all of Pillet's text-book except the skew-arch. Under the division of masonry the lecturer treats of the methods and instruments used in stone-cutting, the principles of jointing, and of vaults, niches, domes and cupolas; the arranging and proportioning of treads of stairs, also vaulted and suspended stairs. Under the division of wood-work, the general rules of framing are considered, the methods of assembling pieces, general principles of roofs and the special ironwork of carpentry. This course also includes the methods of finding patterns of stonework and bevels of rafters, and two problems are given, the one in wood and the other in stone construction. Of those given last year the first was a small railway station, which involved the design of the building, the framing plan of the roof and the principal bevels, also the framing of the stair and the patterns for the front string; the second was a building entirely in stone, to be erected in a public market square and to contain a fountain and other sources of water supply for the market. It was to be a vaulted structure, with the vaulting visible both inside and out, and a decorative motive based upon the structural form of the vaults. In the centre was to be a large stone basin, and around the walls small basins supplied with both warm and cold water for washing purposes. Outside were to be troughs for the watering of animals. The basement was to be used for storerooms, and was also to contain the apparatus for heating the water; a stone stairway was to serve as a means of communication with it. Drawings were required of the plan, facade and section, showing the jointing of the stonework, besides patterns of three voussoirs, one of which was to be from the vaulting of the stairway. A course in surveying, consisting of six or seven lectures and three days' practical field work, is appended to the above course.

The work in construction comprises twenty lectures on theoretical and thirty on technical construction. Burn's text on "Construction" is followed in outline, but in a condensed form, and the formulae which are given are demonstrated whenever possible by means of the mathematics already enumerated. The following outline is very general and the reader is expected to supply many headings which are necessarily preparatory to some of those enumerated. The lectures include internal and external forces acting on beams, application of formulæ to all usual cases, beams of equal resistance, also beams subject to inclined pressures, columns, lattice girders, roofs, calculation of strains and deformations, curved roofs, metal ribbed vaults, expansion, friction, effect of wind, stability of masses and distribution of pressures, retaining walls, problems of stability, applications to foundations in general, reservoir walls, stability of vaults and their supports, curve of the centre of pressure and its application to vaulting.

The technical part includes a description of the materials of construction, methods of handling and transporting them, foundations, rules for masonry work, walls subject to thrust, buttressing, shoeing, piers and columns. Vaults are treated first historically, after which follow descriptions of different kinds, methods of construction, centrings, piers, abutments and buttresses, stone stairs, paving with flagstone, brick and asphalt, and the draining of rain water. The lectures on wood-working include descriptions of woods, methods of preservation, general principles of wood-working, assemblages, walls, floors, scaffolding, roofs, dormers, spires, towers, effect of wind and snow, roof coverings, stairs, joinery and special iron-work. This is followed by lectures on metal work, descriptions of the useful metals, commercial shapes, iron walls and floors, masonry work of floors, roofs, trusses, arches, awnings, glazed roofs, water pipes, gutters, iron blinds and shutters, elevators, grilles, balconies, hardware, plumbing and gas-fitting, heating and ventilating, electric bells and lightning conductors.

Three problems are worked en loge during the lectures on theory, and three general problems are required during the latter part of the course. Besides these problems there is an oral examination on each of the two parts of the course of about three questions. The nature of the problem to be worked en loge is known beforehand, so the student may be supplied with whatever data and formulæ may be necessary. One of these problems called for the design of a lattice I-girder of equal resistance throughout and to maintain a uniformly distributed load and two concentrated loads at equal distances from the end. Given the size of the angle irons, height of web, width and thickness of cover plates and diameter of rivets, calculate the number of cover plates required at the centre and at what points they may be successively discontinued, also the spacing of the rivets for the cover plates and the lattice bars. Another problem was the design of a six panel triangular truss, sustaining dead load only, by both analytical and graphical methods.

The three required during the lectures on technical construction involve design as well as construction. The first usually includes the investigation of a vault, such as: Design a grand stairway leading up to a terrace, the principal landing of the stair being vaulted. Calculate the vault and its buttresses. The second in one case called for the design of one bay of a riding school, the walls to be of half-timbered work, trusses 38 metres centres and 20 metres span. Submit plan, elevation, details of framing, and the calculation of the principal parts. The third is called the general problem, and includes about all the ordinary problems of construction which can be centred in one building. The following one will serve as a sample: Design a museum building, consisting of central glass-covered court, surrounded by galleries, three stories and basement high. On the third floor is to be a library. The basement ceiling is to be vaulted, the other floors to be of iron and masonry, the roof of the court to be of iron and glass, while that of the galleries is to be of wood and metal. There are required complete general drawings, problems of the stability of the vaults, and notes on the calculations. These drawings are quite elaborately worked out and rendered in color, even the construction details having the shadows all cast at 45 deg. The feature of design enters every problem that requires drawing, no matter what the study.

The course in perspective consists of twenty lectures, and is very thorough. Three problems are required besides one en loge. The following may be considered as samples: Design a pedestal bearing a statue, the base to be about 1.5 metres across and either square or circular. Make a drawing of a public place, surrounded by arcades and with a monumental fountain in the centre. No side of the square is to be parallel to the picture plane.

Make a drawing from nature of an ensemble or architectural detail, the drawing to be at least 0.25 × 0.35 metres. The problem given to be drawn en loge last year was the capital, architrave and frieze of the Greek Doric order, without triglyphs. The shadows were also required.

The above is, I believe, a fair representation of the work of the school not classed under the head of design, except the diploma drawing, which is a thesis design and involves details of construction and specifications. A candidate for a diploma is also required to pass quite elementary examinations in physics, chemistry and building law.

The usual problems in design do not include any calculations of construction, as no construction is expected to be shown on the drawings.

POINTS ON PLASTERING.

By "Plasterer."

Perhaps some information on the general practice of lathing and plastering will be interesting. There is undoubtedly much bad plastering, and in every case the mortar and plastering material is blamed. This is not just.

The first essential of good plastering is good preparation to receive it. For plastering on brick or terra cotta, have your work straight and true, the joints rough. Don't use dry press brick, nor terra cotta with smooth face. If your walls are not straight don't expect to get a straight wall in two-coat work—lime mortar cannot be made that is equally good when used half an inch thick and two inches thick in the same wall.

Don't plaster with cement made from gypsum or similar compounds, such as acme, royal, agatite, etc., on Columbian fire proofing, or on Portland cement, unless you have them dry enough to prevent sweating or condensation. Portland or native cements, or even lime mortar is preferable in such work. Don't allow mortar to go on thicker than ¾ of an inch at one time, and have your brick or cement free from dust or dirt. Don't plaster on smoked bricks or old bricks from chimneys; they will stain badly.

In preparing for lathing have your joisting, trimmers, etc., heavy enough to prevent vibration, and strap all large ceilings, using 2" × 2" strapping on 16" centers. If you don't strap, at least have all joisting and studding sized; very much crooked work would be avoided by enforcing this rule. Have all angles made solid. See to this yourself and don't rely on lathers who work by the piece to inform you of the carpenter's defects, and have trouble with him in consequence.

Use white pine lath, seasoned but not too dry. 1⅜" × ⅜" lath are light enough; 1" × ⅜" lath are only fit for use on joisting or studding at 12" centers. 18" breaks are frequent enough, but don't allow lath to break at door posts; the slamming of door or even the nailing of trim will cause a crack here. Don't blame the plasterer for this when you have allowed the carpenter to center his work so as to cause waste of time and lath to avoid it. Don't be unreasonable. Contractors are working at close figures for a living. Blame the right party. When you see a crack at an internal angle just above base, you did not have that angle made solid, and nailing the base caused it to crack.

Lath stains cannot be avoided in two-coat work, and are even more liable to appear when patent plasters are used, as the first coat is put on much thinner to save cost. Two-coat work is also liable to have every lath and joist show through when work gets old you can count them through the plaster.

Lime mortar properly made makes good work, but you can't make a poor plasterer do it. Mortar made and used at once will get as hard if not harder than what is allowed to age. There is of course more danger from lime pitting; there is also a greater danger from the shorter nature of the material that the key will fall from all wall work. These objections are enough to condemn its use, but it is both unnecessary and impracticable to ask that it be made two or three weeks before using. Very sharp sand is not best for ordinary mortar; a good clean sand of sharp grain or a mixture of soft and sharp is better; it requires the strength of cement to bind coarse sharp sand.

Don't allow mortar on lath to be used too soft—you will have no key. Don't have it too rich with lime for same reason. See that it is of proper consistency to require some force to apply it. If too poor (too much sand) key will fall off on wall work. Mortar of proper consistency for good work will crack badly in very hot weather, or if dried too quickly. For second coat on lath or for brick work one-third more sand may be used.

The term "hard white finish" is a misnomer; the hardest lime finish is made with sand. If enough sand is used to avoid use of calcined plaster, work will be uneven in color when dry. Don't allow finishing before base coats are dry—you are in greater danger of lath stains, cracks, lime pits, etc.

These remarks might be continued indefinitely. If they prove interesting I will be happy to give you some more.

THE QUEBEC CASTLE.

In describing the antique castle, several writers have mixed up dates and incidents referring to the Fort St. Louis begun in 1620, with those relating to the Chateau St. Louis, which, after several changes and transformations, assumed that name only in 1647, under Governor de Montmagny. Hawkins is quite correct in saying that "The Castle of St. Louis was in early times rather a stronghold of defence than an embellished ornament of royalty. Seated on a tremendous precipice

> On a rock whose haughty brow
> Frown'd o'er St. Lawrence's foaming tide.

and looking defiance to the utmost boldness of the assailant, nature lent her aid to the security of the position. The cliff on which it stood rises nearly two hundred feet in perpendicular height above the river. The castle thus commanded on every side a most extensive prospect, and until the occupation of the higher ground to the south-west, afterwards called Cape Diamond, must have been the principal object among the buildings of the city.

"When Champlain first laid the foundation of the Fort, in 1620, to which he gave the name of St. Louis, it is evident that he was actuated by views of a political, not of a commercial character. His mind was in better keeping with warlike enterprises than the acquirement of wealth. He was perfectly disinterested in all his proceedings. Foreseeing that Quebec would become the seat of dominion and invite a struggle for its future possession, he knew the necessity of a stronghold, and determined to erect one in opposition to the wishes of the Company of Merchants." The building was commenced in July, 1620. - J. M. LeMoine in the December Canadian Magazine.

WATER CURTAIN PROTECTION.

A somewhat novel system of fire protection has been tried at Boston to save a building from being ignited from adjacent premises. The chief fire station is in a dangerous lumber district, and a five-inch stand pipe has been erected, with connecting perforated pipes running along the front and side of the building near the top. There are also a number of spraying nozzles. By this means a complete water curtain is formed, affording perfect protection. At the trial 1,000 gallons of water per minute was used.

TESTING OF CEMENT.

The Master Builders' Exchange of Philadelphia having reported on standard specifications for cement, basing its clauses largely on those of the American Society of Civil Engineers, Mr. Cecil Smith, of McGill College, Montreal, criticises them in the Brickmaker in the following terms:

1. Specific Gravity.—During the last three years I have tested very carefully about forty brands of Danish, German, Belgian, English and Canadian Portland cements and not one of them has gone as low as 3.00 in specific gravity; therefore, I consider a clause demanding a value of 3.00 for specific gravity is of no value whatever to prevent under-burnt products. Natural cements, also, usually range from 2.90 to 3.05; therefore, there is little use in specifying a minimum of 2.50 for natural cements.—A specific gravity of about 3.09 for Portlands and 2.90 for naturals would really obtain what was intended,—namely, well-burnt products.

2. Fineness.—Why should there be two classes of tests? Surely any two persons can sift cement the same, whether in a laboratory or in a contractor's shanty. What should be specified is that a certain amount of cement should be used in sifting, and that the sifting should be continuous such a number of minutes; then uniformity will be obtained. For myself, if I use 10 ozs. of cement, and sift two and one half minutes on a No. 120 sieve, then sift the residue one minute on a No. 100 sieve, then the residue three fourths of a minute on a No. 80 sieve, then the residue one half minute on a No. 50 sieve, I find the residues are about uniform in size and color. I obtain close uniformity. If only a No. 100 and No. 50 sieve are used, the same method could be employed.

Regarding the actual amount of residue demanded, that is entirely a matter of dollars. Fine grinding must be paid for, but the clause, as set forth in the specifications being dealt with, is so lax as to call forth a protest.

Any natural cement having more than 15 per cent. residue on a No. 100 sieve should be certainly rejected, because they are so lightly burnt as to make it very easy to grind them finely. It is quite easy to obtain Portlands and naturals with only 10 per cent. residue on a No. 100 sieve, and this is the requirement of the standards of Canadian Society of Civil Engineers, formulated in 1894.

3. Checking or Cracking.—No checking when exposed in air or water! How long are we supposed to wait? The report does not say, but from a great number of experiments I have made I would say that cements with a slight amount of free lime in them will stay solid in cold water for several months, but finally crack. The only way to develop "blowing" in a short time is to subject the cement pats to hot air or hot water.

4. Strength.—With ordinary care, neat cement briquettes made in the ordinary way, by using sufficient water to make a plastic mortar, then putting the mortar into the molds with a trowel, and shaking the molds well to drive out air bubbles, will give fairly uniform results; but in making sand tests the method of putting the mortar into the molds is the whole matter; a one week test, three to one, can be made to vary all the way from 25 to 150 or even 225 lbs., depending entirely on the manner of placing the mortar in the molds. Therefore, a clause not stating how this is done is of no value whatever, even if the clause stated that the mortar should be rammed into the molds. There are as many ways of ramming as there are operators, and the result might vary by at least 100 per cent.

Personally, I consider sand tests are of little value, because if the clauses of specific gravity, fineness, blowing (or checking), and neat tensile strength have been sacrificed, then one can predict the comparative sand test value; but if sand tests are wanted, then I believe firmly that there is only one way to make them strictly comparable, and that is to put the mortar into the molds in a soft, plastic, condition, such as is used by masons, and let it be forced into the mold under a uniform dead pressure. This method I have used for over a year, and I feel I can determine accurately the desired knowledge of the actual cementing strength of sand mixtures as used in practice.

The city hall at Chicago threatens to collapse. An official inspection shows that the two ends are settling, and pulling the building apart, which is shown by large cracks through the centre. Immediate repairs are necessary.

GOOD ADVERTISING METHODS.

Mr. Chas. Austin Bates, in his department of criticism of advertising methods in Printers' Ink, says:—

Gara, McGinley & Co., of Philadelphia, have been successful advertisers in a line little advertised. They are roofers and makers of architectural decorations in metal. They make metal ceilings, skylights and store fronts. The inexperienced or unposted observer would say, from looking at the mass of advertising matter that they send out, that they were spending more money than the business would justify. That this is not true is proven by the fact that the business becomes bigger and more profitable every year. And apparently the more money the firm spends in advertising, the more money they have to spend. They have made quite a feature of advertising what I believe to be a very insignificant part of their business. That is the repairing of roofs.

One of the best phrases I ever saw in an advertisement is one of theirs, which says: "We do one thing well. We mend roofs." Another phrase is: "We are leak finders." One ad that they have used has stuck to me, and amuses me every time I think of it. It is a funny ad, and is the exceptional funny ad that proves the rule that all funny ads are bad. It is: "How much better it is to sit by a cosy fireside, and think how much better it is to sit by a cosy fireside than to be on the roof cleaning the snow off, thinking how much better it is to be sitting by a cosy fireside than cleaning the snow off the roof. We are snow removers and leak finders. Gara, McGinley & Co."

The last smart thing the firm has done was to get out a handsome little booklet entitled, "Pointed Suggestions." I think it would have been better to call the booklet "Pointed Suggestions to House Owners," or "Points on Roofs," or something of that sort, letting a man see immediately what the book was about.

It is liberally and suitably illustrated with half-tones of wash drawings. From a mechanical standpoint, there are only a few criticisms to be made. One is that on some pages the matter is arranged in a spotty sort of way. It is broken up too much and isn't sufficiently cohesive. The best thing in the whole book is a thing that certainly deserves praise as a plain and convincing piece of advertising. It is a series of half-tone pictures of Gara, McGinley & Co.'s office as it was and as it is. First there is a picture of an old-fashioned, three-storey brick house, in the architectural style of sixty or seventy-five years ago. The next picture shows this house in process of demolition. The third picture shows the addition of another storey. The fourth picture shows a part of the building covered with rock-faced metal plates. The other part is uncovered, giving the idea of the method of applying the plates. The fifth picture is the finished building, a stately, dignified, artistic piece of architecture, which no one who is not admitted to the secret would ever suppose to be the same house as was portrayed in the first picture. This is a practical illustration of what Gara, McGinley & Co. are prepared to do with other old houses.

Mr. Joseph Bourque, of Hull, Que., is taking action to compel settlement of balance of account of the court house and jail contract, which has been standing for two years.

As a result of a recent accident in Ottawa, a scaffold inspector for that city will probably be appointed. It is proposed to have all contractor's plant inspected and branded, and to insist on its being placed under cover during the winter.

NEW CANADIAN PATENTS.

AMONG the new patents granted in Canada as announced in the last Patent Record are the following relating to the building trade:—

Cleaner for Cisterns—Charles A. Butterfield, Dewitt, Iowa.

Window Fastener—Ernest Peters, Tompkins, Mich.

Door Fastener—M. P. Pirtle and J. W. Miller, Louisville, Kentucky.

Fastening for Window Sashes and Slide Doors—D. A. Crichton, Los Angeles, California.

Fancy Brick, Etc.—The National Opalite Glazed Brick and Tile Syndicate, London, England.

Fire Escape—Wilbrod Bourdon, Valleyfield, Que.

Hasp—Wm. Firfield, Perth Amboy, N.J.

Weather Strip—Chas. M. Becker, Port Rowan, Ont.

Chimney Cowl—Cyrus N. Shannon, St. Cloud, Minn.

Building Brick—Geo. S. Balsley, Detroit, Mich.

Hot Air Flue—Wm. H. Brinker, Pittsburg, Penn.

Sash Cord Catch—John Wheatly, Hamilton, Ont.

Heating Drum—Thos. H. Wilson and Robt. Humphreys, Logansport, Indiana.

Indicator Door Bolt—Wm. S. Burgess, Three Rivers, Que.

Heating and Ventilation System—Wm. Bruce, Leeds, England.

Heating Furnaces by means of Liquid Hydrocarbon—La Compagnie Internationale pour l'Exploitation des Procedes, Lyons, France.

Window Fastener—Laura Hofheimer, Brooklyn, N.Y.

Double Flushing Water Closet—Philip Nicoll, Toronto.

Bath Tub—Robt. M. Wilson, Rome, N. Y.

Brick Kiln—Geo. S. M. Rutter, Canton, Ohio.

Stench Trap—Geo. Dunstan, Lorain, Ohio.

Window—J. A. Cleveland, Duluth, Minn.

Metallic Roof—L. S. Flutan, Dallas, Texas.

Hot Air and Steam Bath Apparatus—Salli Maschke, Berlin, Prussia.

The Laughlin-Hough Drawing Table Co., of Guelph, have received an order from Ottawa for six of their large size tables.

Electricity is being used to operate the large stone saws at the government buildings at Victoria, B. C., now in course of construction.

Mr. J. R. Booth, of Ottawa, has purchased the Reefer stone quarry in Nepean, from which stone will be taken for the new central depot to be erected at the capital.

The contract for 30,000 tons of cast iron pipe for the waterworks at Yokohama, Japan, was awarded to an Alabama iron company. It is said to be the largest order ever given for American iron for foreign shipment.

MANUFACTURES AND MATERIALS

A mortar composed of brick powder mixed with quicklime is largely used in France.

The Maritime Nail Co., with an authorized capital of $50,000, has been organized at St. John, N. B.

The Northumberland Stone Co. has been formed, with a capital of $10,000. The incorporators live in Shediac, Sackville and Botsford, N. B.

Mr. H. Horskin and Mr. Hurlburt have entered into partnership at Bedford, Que., for the manufacture of sanitary ware, general plumbing goods, etc.

Arrangements are about completed whereby the partners formerly interested in the British Columbia Pottery & Terra Cotta Co. will regain the ownership.

The Brockville Pressed Brick Co. are building railway sidings, arranging for the purchase of bush land for fuel supply, and otherwise improving their facilities.

The Union Bank has sold the C. B. Wright brick yard near Hull to Messrs. Arthur, Walter and Thomas Farley for $20,000. The new firm will put in new machinery and operate the yard.

Attention is being directed to large deposits of asphalt which exist on the Athabaska River, N. W. T. Tests made of specimens collected by members of the geological survey show it to be well adapted for the construction of roads, footpaths, courtyards, granary and warehouse floors, and also for roofing.

The Whitton Granite Quarry Co. has been incorporated, with capital of $50,000. The incorporators are: Senator Boldue, Mr. Rufus H. Pope, M.P.; Mr. Louis Israel Frechette, M.P.; Dr. G. H. Lacoureiere, of St. Victor de Tring; Mr. Wilfred Trudeau, of Fall River, and Mr. D. Alfred Roy, merchant, New Bedford, Mass.

A company has been formed in the United States to supply contractors and builders with ready-made mortar. Their buildings at Pittsburg will be seven storeys high, and the mortar will be mixed on the top floor, and when it reaches the ground will be ready for use. It is claimed a better quality of mortar can be thus supplied.

The announcement recently published that a deposit of the finest quality of roofing slate had been discovered in the township of Euphemia, Lambton county, Ont., proves not to have been well founded. Mr. Archibald Blue, Director of Mines for Ontario, has lately visited the locality and found the deposit to consist of ordinary bedded shale.

CANADIAN ARCHITECT AND BUILDER.

(Price of this Number, 35 Cents)

VOL. IX.—No. 1. JANUARY, 1896 { PRICE 20 CENTS / $2.00 PER YEAR.

THE

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journa is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

TO OUR READERS, GREETING.

WITH this New Year Number the CANADIAN ARCHITECT AND BUILDER begins its ninth year of publication. This is the largest, and in many particulars is believed to be the best number of the journal that has yet been published. Placed side by side with the productions of earlier years, it is a gratifying evidence that the journal has maintained steady progress. An expression of our indebtedness and hearty appreciation is tendered to Mr. Ernest Wilby, of Buffalo, N. Y., formerly of Toronto, for the beautiful design which adorns the cover of this number, and to Mr. Henry Beaumont, sculptor, of Montreal, who modelled the design in clay so that a photograph giving the necessary relief effect might be obtained. The skill of both designer and sculptor is more effectively expressed in their work as reproduced in this number than by any words of ours. This is believed to be the first instance in which this method of illustration has been employed by a Canadian journal. A plaster cast taken from the clay model is being exhibited at the annual convention of the Ontario Association of Architects, now in session in the School of Practical Science, Toronto.

Our thanks are also due to the gentlemen who have contributed interesting and instructive articles to this number on a variety of subjects relating to architecture and building. We should be pleased to receive the assistance of a larger number of readers in this direction, not only on special occasions like the present, but throughout the year. In the multitude of counsellors there is said to be wisdom. If every reader would feel himself under obligation to give as well as to receive information, the pages of each number of this journal might be made much more helpful than they have hitherto been. May we not expect an improvement in this direction this year?

We appreciate also the support which we have received in the form of advertisements from manufacturers and dealers in all classes of materials employed in the erection of buildings, and without which it would be impossible to supply a publication of this character at such a small subscription price. The advertisements form a valuable directory to which the architect, engineer and contractor may at all times conveniently refer. Much care has been given to make the advertisement pages and attractive an interesting feature of this number, and we bespeak for them the careful examination of our readers.

HAMILTON ART STUDENTS' LEAGUE.

ART circles in Hamilton have been stirred into somewhat unwonted action this season by the organization of the "Hamilton Art Students' League," formed on the usual lines of such art clubs with the view of mutual improvement and help as well as the promotion of art and good fellowship among amateurs and professionals. It is not entirely a new departure, for some years since there existed a Sketch Club in the Ambitious City comprising most of the wielders of the brush and pencil then active, and being known as the "Black and White Club," holding its meetings in the studios of J. R. Seavey and exhibiting occasionally groups of sketches by the members.

The new movement began in November last at a largely attended meeting of ladies and gentlemen held at the Canadian Club, the prospect being so promising that without delay the organization was effected. Mr. J. R. Seavey, the artist, was elected President; Miss Clara Galbraith, Vice-President; Mr. C. L. Wright, Secretary, and Miss Tutty, Treasurer.

A commodious and centrally located atelier at 8 King street west was secured, lit by electricity. The main room being formerly a large photographic operating room with skylight, makes it convenient for both night and day work. There is room for a semi-circle of 25 members to sketch in the front row about the model throne.

A Board of control, consisting of active and ex-officio members, manages the League, while a House Committee, elected each month, supply models and attend to details. Two evenings each week are devoted to drawing and painting from life, the monthly dues being one dollar, which covers the expense of models, rent, etc. Associate members who have a vote in the elections, and the entree of the exhibitions, pay an annual fee of two dollars. No instructors are at present employed, but as the League is composed of many enthusiastic artists and students, the work is earnest and thorough. About thirty-five active members are enrolled, many of whom are ladies.

The first week in June the annual sketch exhibition will be held in the rooms, and in December the annual exhibition of finished work by the members, active and associate, at the Canadian Club.

House of H. Vincent Meredith, Montreal.

MONTREAL.

(Correspondence of the Canadian Architect and Builder.)

It is evident to whoever has studied the development of architecture in this province, or at least in Montreal, that it has perceptibly retrograded during the last decade owing to the wholesale building by speculators, without the aid of the architect, or at least, intelligent architects. From the foundation of this country up to about thirty years ago we can easily trace the influence of the architecture of the older countries of Europe, especially of France in the first period and England in the second; while since then we have reflected all the mixed styles which have held sway in the United States, from the Neo-Grec to the revival of Colonial; or in other words we have built regardless of style at all. This is the case with the majority of structures of modern construction.

Stores on St. Catherine Street, Montreal.

American architecture commenced to get a foothold here, with the erection of the Standard building on St. James street, which was built from the design of an American architect. Whether people were prejudiced against the architecture done by local architects is an open question, but it is nevertheless true that since the erection of that building many works of importance have been entrusted to American architects, as exemplified in the New York Life building on Place D'Armes, the Y. M. C. A. building on Dominion Square, and in the more recent example of the Board of Trade building on St. Sacrament street, which seems to have had the effect of forcing our architects to study the architecture of our neighbors in order to meet the popular demand and craze of the day for Americanism.

Merchants' Bank of Halifax, Montreal.

Branch Bank of Montreal, Montreal.

Westmount, formerly called Cote St. Antoine, is the locality for excellence where we will find in large numbers examplos of American domestic architecture, which, it cannot be denied, is especially fitted for this country.

Much difference of opinion will exist as to whether Montreal should be blamed or praised for its frequent change of styles, but it will be agreed that it is not so much the question of style we should advocate as that we should strive to obtain in whatever style we choose the highest possible excellence by studying the same thoroughly and intelligently.

Where architecture in Montreal has retrograded has been in the erection, during the last ten or twelve years, of dwelling houses on a grand scale by speculators, from the plans of an inferior class of architects, or more often still from the plans of builders. This class of building far outnumber the better class, which accounts for the distorted perspective one meets with in the streets of some localities.

A few illustrations are here given of some of the best buildings of recent erection, for photographs of which we are indebted to Mr. Cajetan Dufort, architect, of Montreal. Fig. 1 represents the residence of H. Vincent Meredith, at the corner of Pine avenue and Peel street, Mr. Edward Maxwell, architect, the work of which is finely executed. The walls are built in fine pressed brick, red in color and relieved with sand stone trimmings. Fig. 2 represents two stores with dwellings above, on St. Catherine street, near Mansfield street, Messrs. Cox & Amos, architects, built in sand stone of two different colours. Fig. 3 is the Merchants' Bank of Halifax at the corner of Notre Dame and Seigneurs streets, Mr. Edward Maxwell, architect, the ground floor of which is in olive green sandstone and the remainder in buff pressed brick. Fig. 4 is the branch of the Bank of Montreal, situated on the opposite corner from the last named building, entirely built of red sandstone. Fig. 5 represents the new building of the Bank of Toronto, at the corner of St. James and McGill streets. Mr. A. T. Taylor, F.R.I.B.A., is the architect of these structures.

Bank of Toronto, Montreal.

OFFICE METHODS FOR ARCHITECTS.

A PROGRESSIVE firm of architects in Western Ontario, have by request, favored us with particulars of their office methods, including copies of their printed forms for various purposes. These forms and particulars are given herewith

FORM OF ORDER FOR EXTRA WORK.

in the hope that they may prove of interest and value to the architects of the country. We shall be pleased to receive expressions of opinion upon them and suggestions for their improvement :—

PROGRESS CERTIFICATE BOOK.

For convenience two kinds of certificate books are used, viz : progressive and final in conjunction with a "Contract Ledger."

The certificates in both books are consecutively numbered and a ledger folio space is left on counterfoil to mark the page on which the building account is kept.

The perforated stubs are large enough to enter all information relating to the certificates. The memorandum in lower left hand corner for noting the amount of contract previously paid, etc., and balance due, if properly filled out will serve as a short general statement to the client. Contractors can receipt payment at the bottom of the certificate.

FINAL CERTIFICATE.

The final certificate detailed statement somewhat differs from the "progress," a space being allotted for extras and deductions, which greatly facilitates obtaining a balance where extras and deductions are concerned.

Some final books contain under credit column a complete list, month and dates of progress payments, but if the contractor's ledger is regularly posted it is unnecessary to repeat that work for owner's benefit.

ORDER BOOK FOR EXTRA WORK.

When extra work is desired by client or his architect, a price arranged and an order given beforehand will lessen the time spent on the final adjustment of account.

CONTRACTORS' LEDGER.

The Ledger consists of a 3 money column or bank ruled book. The top of page gives name of client, kind of building, street, location, in city or town. Across

FORM OF RULING FOR CONTRACTORS' LEDGER.

June Wednesday, 12, 1895. (163-202)

Hour	Client	Remarks	Ledger Folio	$	c.

FORM OF DIARY.

.....

When made Month	Day	Description of Drawing	When rec'd Month	Day	To Whom Delivered	Returned

FORM OF RECEIPT BOOK FOR DRAWINGS.

the page the name of the contractor is inserted, with sufficient space allowed between it and the next amount to admit the placing of amounts of his account, and so on with all parties engaged on the works.

It can be readily seen that in closing a building account the architect has a complete list, avoiding the tedious task of searching through the counterfoils of a score or more certificates, occasionally missing some account from final statement the commission on which, overlooked on each job during the year, might involve a considerable loss to an architect's bank account.

A second class of ledger is ruled and printed for noting in a condensed form the entire contracts relating to a job or structure. One column contains all of the information relating to the masons, another to the carpenter, etc. Payments made are quickly entered on the lower half of the page. It is unnecessary to refer to the contract or to the certificate book for information. If carefully kept, this book will save much valuable time, both for immediate and future reference.

DIARY.

This book may be had from any stationer, and ruled by hand to suit.

The first column denotes the hour or time occupied, next the name of client or building, remarks, ledger folio and money columns. The lower half of page may be used to keep draughtsman's time on special work. The time spent on each drawing is placed under the remarks column. The dollars and cents columns can be used for entering the cost of the drawing, or they may serve for noting expenses of every description, such as car fares, travelling expenses, etc., incurred while superintending buildings or other work.

As extensive and complicated work usually requires more time than at first estimated upon and extra work frequently is added, disputes with clients relating to charges for time spent on their orders can be satisfactorily adjusted. The record always speaks for itself, and if necessary the men who were engaged on the work can be called to verify their figures and time.

Very little time is wasted by an employee in making the entry, as nothing need be written but the description or number of work and the number of hours spent thereon.

The diary may also be used to mark the general business in, and posted into a ledger.

At the top of page are written name of owner, class of building and location. When drawings are taken out of the office a receipt taken at the time of delivery will greatly assist in bringing them back, and a history of the case may be obtained without delay or inconvenience.

SPECIFICATION COVER.

A neat form of keeping specifications clean and easily handled is by using the "Lawyer Brief Covers." The marginal references would then be made in the centre of the paper between each paragraph.

REMINISCENCES OF THE ARCHITECTURE OF SICILY.

By A.C. Hutchison, R. C. A.

The growing towers like exhalations rise,
And the huge columns heave into the skies.
—Pope.

THE Island of Sicily, so rich in its historical associations and in examples of the architecture of the different people that from time to time have been its rulers, from five or six centuries B. C. down to the present day, was visited in the month of February last, but in so hurried a manner as to only afford time to glance at buildings with whose history former study had made me somewhat familiar. Seeing many of these buildings, though but the skeleton of their former glory, was like renewing old acquaintances, and only served to whet the appetite and induce longing for an opportunity for more minute examination and leisurely study.

This island, which has had such a varied and chequered career during the 2,500 years with which history makes us acquaint, and has served under many and varied masters, some of whom, highly advanced in art, have left us monuments which, though now shorn of their original beauty, bear mute testimony to the status in art, skill in construction, and power of the people who erected them.

The imprint of the art of the different nations and people who from time to time have held sway on the island, and whose nationalities and art instincts were so widely different, being thus brought together within small geographical limits, enables one to study a great variety of styles, and the influence which in some cases one had on the other, without having to travel very far.

So many of the more important buildings of this island have been minutely described and illustrated in works which are in the hands of many of your readers, that it would be useless to attempt any detailed description in a short article. I will, therefore, only briefly describe the representative buildings of the different styles, and the impressions produced on coming in contact for the first time with the art of the Orient and Occident, where they met on this classic island.

Naturally Greek architecture will first claim attention, and if along with the examples of this art to be found in Sicily, we include those at Paestum in southern Italy, we find a group of buildings that for size and skill in construction, rival those of Greece itself, and for beauty of design are only surpassed by those of Athens. Greek architecture in Sicily and Italy, as in Greece, is illustrated in temples, while the constructive and engineering skill of the Greeks is shown in city walls, forts, and aqueducts, which remain to the present day. The principal groups of temples in the island are to be found at Selinunto, Segesta and Girgenti, and if we include with them the temples at Paestum, we have in all fourteen buildings illustrative of this architecture. Some of these buildings remain nearly entire, while others are in utter ruins and can only be judged by the remains of the columns, capitals and entablatures, which lie round the site of the temple of which they were a part. Syracuse, in the south east of the island, the largest and most powerful of the Greek cities, no doubt contained many temples commensurate with its wealth and importance, but so utter has been its destruction that, with the exception of a few columns of a temple incorporated in the cathedral of the modern city, and a few fragments near the seashore, nothing remains of its temple architecture.

The erection of the temples in Sicily, of which we have remains, dates from about 600 to 400 B. C., thus covering the best period of Hellenic art. Portions of the entablatures, with the sculptured metopes of several of the temples at Selinunto, were removed some years ago to the museum in Palermo, where they are now set up in a large hall. The sculptures on these metopes cover a period of about 200 years, and as the latest in date is about the time when Hellenic sculpture had attained to nearly its greatest excellence, we can in the study of them trace the development of sculpture from early beginnings to its highest development. The largest of the Sicilian temples is one at Selinunto—and if I am not mistaken the largest of all Greek temples. It measures about 370 feet long by 175 feet wide. The temple of Zeus at Girgenti only lacks a few feet of the same dimensions. The intercolumniations of the latter temple were so great that no single stone could be found of sufficient size to form the architrave. To overcome this difficulty, the columns on the sides of the building, instead of being detached, were attached to a wall from which they projected a little over half their diameter. The wall to which they were attached was carried up to the top of the capitals and formed a support for the architrave, which in each intercolumniation was composed of several pieces and overhung the wall about half a diameter. In the end or joint of each stone of the architrave is a square sinking three or four inches wide and deep, made in the form of the letter U; these were probably used for placing the rope or sling in, with which the stones were hoisted to their position, the form and size of the recess allowing for the rope being withdrawn when the stone was set. The stone used in the Sicilian temples is coarse grained and incapable of being worked to a smooth surface. They appear to have been covered with a thin coating of stucco, which was probably painted. The ashlar forming the walls of the cells of some of the temples at Girgenti is so closely jointed that the point of a pen knife can not be inserted in the joint, and the stones appear to have been set without mortar or cement.

The temples at Selinunto and Paestum, standing, as they do, all alone in a solitary plain far removed from habitation or life, present a picture of desolation that is difficult to describe; while the four temples at Girgenti, though placed in the midst of more pleasing surroundings, being situate in line on the crest of a ridge along which once stood the massive city walls, and now surrounded by olive groves, stand solitary reminders of departed greatness.

Besides the temples which tell the story of the art of the Sicilian Greeks, there are remains of city walls, forts, quarries, etc., at different places on the island, which is evidence of their skill in engineering. The most extensive remains of this character are to be found at Syracuse, the most important of the cities of Magna Graecia. Probably the most interesting of these ruins is that of Fort Euryelus, situate at the extreme west of the ancient city, on the apex of a ridge of rock from which the whole of the city could be overlooked. All that now remains of this ancient fort are the foundations and base of the four towers which formed the angles of the fort. These foundations are of the most massive description and composed of huge blocks of dressed stone. Extending from one of the towers, the wall which enclosed the south side of the city may be traced along the crest of a ridge which formed a natural defence on that side; this was also composed of large blocks of hewn stone. Below the fort itself the rock is honeycombed with passages wide enough to permit the passage of cavalry, and vaults to contain stores. These passages and the fort were cut off from the continuation of the rocky ridge by a deep moat cut through the solid rock. This moat was crossed in times of peace by a movable bridge supported in the centre on a pier of hewn masonry, which stands to the present day. About an hour and a half's walk from the fort, over a plain covered with piles of stone, presenting a most desolate appearance, we come to the remains of an extensive theatre. As we pass over the piles of stone in our walk, we can trace here and there the foundations of houses of the ancient city, and can define the width of some of its streets. Of the architecture of the theatre nothing remains. The foundation of the proscenium and stage and the semi-circular tiers of seats, cut in the rock on the face of a hill, can be distinctly seen. In rear of the theatre a small mill daily grinds corn, the power being two turbine wheels, driven by water, conveyed to them through one of the ancient Greek aqueducts.

Two large quarries, from which stone for the ancient city was obtained, are of great interest, on account of the extent of the excavations and the fantastic caves and grottoes that were formed in the rock as the stone was extracted. The marks of the picks used in cutting the rock (the same kind of tool as used in Sicily at the present day) are plainly to be seen.

Besides the theatre at Syracuse, there are the remains of a Greek theatre at Taormina on the east coast, but as the columns and walls now remaining have been restorations during the Roman period, they may be classed as Roman rather than Greek architecture.

In the long interval that elapsed between the overthrow of the Greek power and the advent of the Saracen in the island, an interval during which Carthage and Rome were in succession its rulers, followed by barbarians, ostrogoths, and then by Byzantine power, none of whom, except the Romans, left any imprint of their art, the remains of Roman art are very meagre; with the exception of the remains of a few arches of an aqueduct, an amphitheatre, a bath and small temple, and a few isolated columns at Syracuse, and the remains of Greek theatres restored and Romanized at Taormina and Catania, there is little else to tell that this great power ruled over Sicily.

With the advent of the Saracens in the 9th century, a new life was given to the dead, lifeless art that preceded their coming. New forms of construction and ornamentation were introduced; mosques took the place of the Christian churches which had superseded heathen temples. Of the mosques and other buildings of the Saracen period we have no remains by which to judge of the style. We can, however, judge somewhat of its spirit by the influence it exerted upon the Christian or Norman architecture which superseded it in the 11th and 12th centuries, and still later upon Gothic art.

In the 11th century the art of the east and west first came in contact in Sicily, and while the crescent went down before the cross, the change did not annihilate Saracenic art. Mosques gave place to churches, but the influence and spirit of eastern art remained, softening and modifying Christian architecture, represented by the heavy sombre Norman with which it first came in contact. Under this influence the heavy massiveness that characterizes Norman architecture, as practised in its Northian home, gives place to lighter forms and modes of ornamentation, and the dome takes the place of the semi-circular vault, or is used in conjunction with it. In the cathedrals of Palermo and Monreale, more particularly in the east ends, we find examples of this modifying influence in the forms of mouldings, and in the decorations of the plain surfaces of the walls and arches by the insertion of black marbles in geometrical forms. In a more marked degree we see the same influence in the church of St. John, near the Royal Palace, erected during the Norman period, and in which domes are the dominant feature. The church of La Matorana, near the centre of the city, is a curious mixture of Norman and Saracenic details. As a mosque occupied the site of the present church, the materials of it were no doubt used in the erection of the Christian building. Adjoining the church is a Norman chapel in which the nave is covered by these semi-circular domes, supported on six columns of marble, two of them taken from some heathen temple, two of Saracenic or Byzantine design, and the other two of Norman design; in each case the columns rest on Norman bases. The arches and domes of this chapel have been stripped of their mosiac, so that their construction is plainly seen.

In the royal palace, the Capella Palatena, also built in the Norman period, is one of the most interesting chapels to be seen anywhere. It consists of a nave with aisles, the east bay of nave being rather larger than the others, and surmounted by a dome. The whole of the walls, arches, vaults and domes are covered with the most beautiful mosaics, surpassing even those of St. Marks in their richness. These mosaics, with the details of the nave columns, the pointed arches, and the screens enclosing the choir, all indicate the preponderating influence of Saracenic art in this most beautiful chapel.

Gothic architecture scarcely affected Sicily. With the exception of the cathedrals at Monreale and Messina and one or two churches and part of the cathedral at Palermo, there are no examples of any note. Even in these examples Saracenic art is so interwoven with the gothic as to make it difficult or almost impossible to fix the date of erection by the architectural features, as can so readily be done in buildings of the Gothic period in France and Britain.

Of the buildings of the Renaissance I will not write. While there are a few good examples here and there, none of them are of any special note.

The Court of Appeal at Toronto has recently given judgment sustaining a former judgment of the Ottawa courts in awarding damages to Mr. Brune, the contractor for the isolation hospital on Porter's Island, against the city of Ottawa, for breach of an implied contract on their part to return to the contractor the work in the same or in no worse condition than at the time of the suspension of the said work by the defendants.

WHAT A COUNTRY BUILDER SHOULD KNOW.

By F. T. H.

Semblant art shall carve the fair effect
And full achievement of thy great designs.
—Prior.

TALKING some time ago to a country builder, or rather to a man who styled himself a "builder and contractor," I was somewhat surprised to discover that he had but very little knowledge of the improvements made in building matters during the last ten years. He came to town to buy glass, hardware, paint and nails, for a farm house he was building some twenty miles away; and he turned up his nose at the hardware merchant who showed him wire nails, loose joint wrought butts and steel clad mortise locks with solid knobs. He wanted "no such new fangled stuff in any building he put up." The old cast butt, the clumsy cut 10 penny nail, and the comparatively worthless cast rim lock, and its equally worthless companion, the mineral knob, were to him all that could be desired.

Endeavoring to persuade him of the superior qualities, durability and economy of the later makes of hardware, elicited from him the expression that "he knew his business, and didn't want any city fellow to give him pointers." I dropped him as a hopeless case, and afterwards discovered that he made it a boast that "he never took any stock in fellows that read books and papers to find out all about building. He learned it all when he was a young fellow, and that is the reason he knows it all."

Unfortunately, too, many country builders are imbued with the same spirit as our friend. They have arrived at a certain point a wall of prejudice, as it were—and beyond that it seems impossible for them to get. It is not my purpose to enquire into the reasons of this condition or prejudice, for I do believe there are reasons, psychological or other, that are accountable for the state of mind the country builder seems to drift into, to his own and to his employer's disadvantage, and it will be my object in this short essay to offer some suggestions to my country brother, by which, I am persuaded, if he adopts them, he may better his own condition and give better and more satisfactory service to those who honor him with their patronage.

As farm houses, stables, barns and the other necessary out-buildings on a farm are generally planned by the owner and the builder jointly, or by the builder alone, it is incumbent that the latter should have some knowledge of drafting, that he should, at any rate, be able to sketch on a board with a lead pencil, to some workable scale, a plan and elevation of the proposed work. Such sketches, no matter how rudely executed, if correct to scale, will give the owner an idea of what he is going to get, and to the builder himself they will prove of inestimable value, both as a guide for obtaining his quantities and also as an object lesson in suggesting the best method to set to work to build it.

The country builder should also possess some knowledge of the "fitness of things," a quality that will enable him to design a house, barn or stable, with some degree of good taste. At any rate, he will not create a monstrosity. He should have a fair knowledge of figures, and should be especially expert in the mensuration of surfaces, for largely on this knowledge will depend the accuracy of his taking out the quantities, and his consequent estimate of cost. That he should have some knowledge of mason work, limes, mortar and sand, goes without saying, inasmuch as foundations, cellar walls, piers, cisterns and other stone work will often be under his supervision. It follows also, that he should be posted on plain brickwork, even if he constructs nothing more pretentious than a frame building, as he must see that the chimneys, fireplaces and flues are properly and economically put up and finished. If he is fortunate enough to be called upon to erect brick buildings, he should make himself acquainted with the various kind of "bond" used in brickwork, the quality of mortar required, and the necessary terms used, in order that the bricklayer may understand that the contractor knows just what he wants. The same with regard to the plasterer's work. While it is not necessary that he should be a chemist, yet he should be fairly posted regarding the qualities of lime and sand, so that he would be able to prevent the introduction of inferior materials in the work if necessary; in fact, he ought to be able to see at a glance the difference between good, bad and indifferent materials and fitments of all kinds—knowledge he can only obtain by expending effort and study.

As the country builder is generally the person who not only builds, but also who designs the farm house, he should possess knowledge enough of sanitary plumbing, drainage and conditions to be able to advise the owner correctly on these important subjects. He should not leave the laying out of the plumbing to a plumber, unless the latter is an expert or has devoted considerable study to the subject; then, of course, the whole plumbing and drainage had better be left for him to arrange. If the building, whatever it may be, is to be heated with a furnace placed in the cellar or basement, the builder should have a definite understanding with the parties furnishing the furnaces as to the position of pipes, ducts and registers; for nothing destroys the strength and harmony of a house more than to cut for pipes, ducts and registers, after the building is nearly completed.

As the heating and water service of a house in Canada are important matters, the builder should inform himself as to the different kinds of appliances, their efficiency, their cost, and the fuel they consume items the house owner will require to know before purchasing. As wind mills are now in common use among farmers for pumping and other purposes, a knowledge of them is indispensable, and as they enable the house-owner to have a water service if he so desires, it is essential that water pipes should be provided for as the building progresses, and as it is likely the builder will be asked to estimate and provide for this service, it follows he should be able to do it intelligently, for if he does not some one will be the sufferer.

While a chemical knowledge of paints, oils and coloring pigments is not necessary, yet the contractor should be able to distinguish the good from the poor, and should have on call a full knowledge of the cost of the various brands. He should also be able to tell his employer what colors harmonize, what are contrasts and what are suitable to the work in hand—matters that will require but little effort on his part to understand, if he applies himself to the proper sources. It is also essential that the contractor should possess some knowledge of proportion. It is not to be expected that he is to take a regular course, or make a special study of Greek examples, but he should at least know a few of the elementary principles of proportion that may be obtained from many of the low-priced architectural works now in the market. This knowledge is necessary in laying out windows, doors, stairs, and the sizes of rooms, and in a more aesthetic sense, in proportioning cornices, plinths, bases, capitals, mouldings, and the thousand and one other things required about a building.

So far I have said nothing of lumber and timber required, for as a rule, in this Canada of ours, it is the carpenter who is called upon to design and build the farmer's house, barn, stable or other outbuildings, and it goes without saying that so far as the wood employed in the building is concerned, he knows, or ought to know, all that may be said about it here, so far as quality and durability are concerned; but, under this head it may not be out of place to say that he sometimes lacks a proper knowledge of the prices charged for manufactured wood-work. Like many other manufactured goods, factory wood-work is subject to variations in price, and the difference in their price may materially affect the profits expected in a building, and this makes it important that a correct knowledge of prices current be obtained before an estimate is given. The same rule applies to hardware, glass, paint, and in fact, to everything employed on or about a building.

The next thing to be considered is, "how is the country builder to obtain the knowledge suggested in the foregoing?" At first sight it does appear as though it would cost considerable in money, energy and time to acquire this knowledge. I think, however, I will be able to show that with the aid and good will of the country builder, it will not require much energy, less money, and but a little effort to reach the desired goal. In the first place the "country builder" should subscribe for an architectural paper, similar to the CANADIAN ARCHITECT AND BUILDER, or more than one if he can afford it. This will keep him posted as to the various styles of building in vogue, methods of construction, new materials, new appliances, and all that is going on in the building world. It will also bring the builder face to face with the dealers in the numerous requirements for building purposes, if he scans the advertising pages, such as heating apparatus, hardware, glass (white, stained or plate), bricks, tiles, roofing materials, finished wood-work and plumbing fitments. Letters or postal cards sent to their manufacturers or dealers (always mentioning the journal from whence the address is obtained) will be sure to bring by return mail all the information possible regarding the goods mentioned in the advertisements. By looking over the advertising pages carefully, the builder will be sure to find the name and address of some party or parties who make or deal in the goods required, and by following this method a very useful and a very interesting collection of catalogues, circulars and price lists may be secured, that will prove serviceable to both builder and manufacturer. So far as heating appliances are concerned, I may say that many of the prominent manufacturers issue catalogues of their work that are really a credit to the firm and to the house publishing them, and to the recipients they must prove of great advantage, as they not only show the heater and its construction, give its price, weight and capacity, but frequently give plans for piping with full descriptions, size of pipes, etc., etc., and ofttimes easy and intelligent essays on the principles of heating and ventilation. A little study of these catalogues and a memorizing of sizes, capacities and prices of the goods catalogued, will make the country builder an authority on such matters at once, and this end can be obtained with a minimum of effort and cash.

With regard to the other requirements mentioned, I may say that I append a list of books which cover the ground, and which in my opinion are best suited to the wants of a country builder, who has not had the advantage of a liberal education or a city training.

I do not offer this list as the best of the kind to be had, but as the best for the purpose discussed. For general purposes either Gwilt or Nicholson would be preferred to Loudon, but, as the latter's "Village and Farm Architecture" just answers a country builder's wants, I name it as the main book he should possess after his monthly architectural journal or journals.

LIST.

The Canadian Architect and Builder, per year	$ 2 00
Loudon's Village and Farm Architecture, price	8 00
The Canadian Contractor's Hand-Book, price	1 50
The Builders' Guide and Estimator's Price Book, price	2 00
The Painters' Hand-Book, price	25
Plaster, How to Use and How to Make, price	1 00
Plumbing, Heating Drainage and Ventilating, price	3 00
Hardwood Finisher, price	1 00
Total	$18 75

With this expenditure, to which will require a little brains added, and some application, the country builder may equip himself with sufficient knowledge to become an authority on farm buildings, which should redound to his profit as well as to his fame. Loudon is brim full of excellent ideas that the bright and snappy contractor will avail himself of, and his treatise on stone and brickwork contains ample food for all the reasonable wants of country practice. The other books, besides being instructive, will guide the contractor on correct lines of estimating, which, if followed, will prevent him from taking work below its actual value, a custom that has ruined many "A Country Builder."

ANOTHER dispute on a school house case is reported from East Toronto. The School Board having determined to wait until next year before erecting a school building suitable to the wants of its population, trouble arose with the architect. His plans for a four room section of a 12 room school were accepted by the Board, the understanding being that the cost should not exceed $6,000. The lowest tender received, however, was in the neighborhood of $8,000 and because of the great discrepancy the Board returned the plans. The architect now asks for some $400, but the Board thinks a tenth part of this sufficient. The matter has been referred to arbitration.

THE Supreme Court of Louisiana held, in the recent case of Maas vs. Succession of Hernandez, that where a contract for a fixed amount is entered into between the owner of the property and a builder according to certain specifications to which a plan is annexed as explanatory thereof, no charge, in the absence of an agreement to that effect, can be made for extra services in the preparation of the plan; that the builder appears in the transaction not as an architect, but as a contractor, and that a builder claiming renumeration over and above the contract price of a building for certain labor and material as having been furnished for extra work, must establish with reasonable certainty that they were used for that particular purpose.

BUILDING IN CANADA IN 1895.

REVIEW OF THE SEASON'S OPERATIONS IN THE LEADING CENTRES.

FOLLOWING its usual custom, the ARCHITECT AND BUILDER presents herewith a review of building operations in the leading centres of Canada for the year 1895. The hopeful feeling which existed at the beginning of the year has, we regret to say, not been realized to the extent which could be wished. Business has not experienced that revival which was anticipated, and as a result neither corporations nor individuals have felt justified in launching out into enterprises which involved the expenditure of considerable sums of money. Nevertheless, at some points there has been considerable building activity, notably in Toronto, where the disastrous fires of last January left blanks in the business part of the city which could not be allowed to stand unfilled. The low price of material, especially lumber, has induced a certain degree of activity among those possessed of capital, this remark applying more to residential than to business property. As compared with the previous year the reports which have reached us would seem to indicate a falling off in the value of buildings erected, taking the country as a whole, though it is impossible to arrive at anything like accurate figures, especially in the rural districts.

TORONTO.

We cannot convey a better idea of the building operations of the city of Toronto for the year than by giving a list of the permits issued by the City Commissioners's department, which will show at a glance the number, class of building and value. As will be observed the permits numbered 371 and the value considerably over a million and a quarter dollars, a very respectable showing for a year when money was tight and the encouragement to build, especially business premises, not great. Of course quite a proportion was the result of the disastrous fires, and a good many of the permits were for alterations and repairs, but these in many cases amounted almost to an entire reconstruction. Here is the list:—

		$. c.
75	Brick Dwellings	194,700 00
25	Brick Fronted and Rough Cast do	24,700 00
105	Alterations to Dwellings	59,395 00
13	Brick Stores	25,450 00
37	Alterations to Stores	79,000 00
12	Factories and Workshops	80,125 00
11	Alterations to Factories	41,200 00
6	Warehouses	55,500 00
8	Alterations to Warehouses	28,000 00
5	Alterations to Office Buildings	16,500 00
9	Schools and Alterations to Same	87,100 00
4	Churches and Alterations to Same	34,500 00
2	Fire Halls	10,700 00
8	Hotels and Alterations to Same	33,425 00
21	Stables	18,375 00
2	Alterations to Theatres	9,200 00
2	Charitable Institutions	27,000 00
2	Exhibition Buildings	6,500 00
5	Storehouses	8,200 00
1	Simpson Building	200,000 00
1	Osgoodby "	35,000 00
1	McKinnon "	45,000 00
2	Globe (2) "	32,000 00
1	Jamieson "	27,500 00
1	Dental College	29,000 00
1	I. O. O. F. Building	130,000 00
11	Miscellaneous	8,740 00
371		$1,346,810 00

By far the most important building in the above list is the departmental shop for R. Simpson, built with iron skeleton, encased with brick and fire resisting material. The McKinnon building is also of the skeleton type. Such buildings are expensive, but they have manifest advantages, and are likely to grow in favor as wealth becomes greater. The Globe building is of the same class.

Of the sum set down for churches, by far the largest portion is for the new synagogue, not yet built, though the permit has been taken out. It is to cost $25,000. Toronto has not added much to her ecclesiastical architecture during the year.

The two charitable institutions are the House of Providence and the Fegan Boys' Home. Neither of them present any very striking features.

Two new fire halls figure among the new buildings. They are situated on Dundas and Richmond streets. The former contains apparatus for the protection of a part of the city which is entitled to fuller projection, the latter provides accommodation for the new apparatus procured after the fires of last winter.

The principal new manufacturing buildings are those for the Toronto Lithographing Co., the Metallic Roofing Co., the Gendron Manufacturing Co., and a large addition to Kemp's stamping works.

A considerable sum has been spent on eight hotels. The new building on the corner of Church and Carleton streets represents a large proportion of this outlay.

The Jamieson building on the corner of Yonge and Queen streets, which forms the subject of an illustration in this number, is a good specimen of architecture for mercantile purposes.

The Foresters' Temple, in course of erection, will be one of the most striking of the season's additions to Toronto's modern structures. It is the most expensive by far for which a permit has been taken out, with the exception of the Simpson building.

Considerable progress was made with the new municipal building, and it is now almost ready for the roof. The new Union Station has been completed and occupied.

There have been a number of handsome residences erected. Brick is the prevailing building material for these as well as for business blocks. The class of brick is improving.

Though Toronto has not recovered from the disastrous effects of the boom days, a substantial advance has been made in her growth the past season, and she is yearly assuming a more metropolitan appearance.

MONTREAL.

The year 1895 was an exceedingly poor one in Montreal for those engaged in building operations. Although 1894 was an unsatisfactory year, 1895 was much more so. Comparison can best be made with the aid of figures, which speak more eloquently than words:—In 1894, 382 permits were issued, representing an aggregate value, according to the Building Inspector's report for the year, of $1,634,900; while in 1895 only 109 permits were issued, representing an aggregate value of about $900,000.

The buildings erected are classified as follows: Dwellings, residences and stores, 98; warehouses, 2; convent, 1; school, 1; departmental store, 1; miscellaneous, 6. The principal buildings now in course of construction being not very far advanced, only a small proportion of their cost can be included in the year 1895, as, for instance, the Canada Life Building and the Bell Telephone Building. The Departmental store now in course of erection, mentioned above, is that of Messrs. Ogilvie & Sons, at the corner of Mountain and St. Catherine streets. The convent is that of the Camelite Congregation that can be better termed monastery as it will not receive any pupils and is simply destined as a place of retreat for the ladies of that congregation. The school is the one erected by the Sisters of the Congregation on Roy street.

OTTAWA.

At the Dominion Capital building operations have been about the same in extent as in 1894, and represent an outlay of about $325,000. There has been a considerable expenditure by the city for permanent pavements, some $80,000 having been spent in that way. The new Union Railway station on the canal bank has necessitated a large outlay for approaches, etc., and a handsome building will be erected the coming year, but at present a temporary building only occupies the site. The work on the approaches, etc., represents an expenditure of about $200,000. The principal business buildings erected during the year are the Carbon Works, $35,000; Cluff's Hotel, $35,000; Cousin's office and shop building, $35,000; and a car shed for the Electric Co., $12,000. The amount expended on business buildings will foot up some $157,500, and on residences $115,500. The finest under the latter class is that erected by Mr. T. Birket, at a cost of $20,000. Public buildings represent an outlay of about $52,000, half of which was for additions and extensions. The material used was principally brick and stone, the residences being chiefly of the former material with sandstone dressings. The price of material and labor was about the same as in 1894.

The architects under whom the building in Ottawa was principally carried out were Messrs. Arnoldi & Ewart, E. L. Horwood, F. J. Alexander, A. M. Calderon, and Wm. Hodgson, and the

contractors were Messrs. Holbrook & Indertaut, P. Kennedy, A. Garvock, W. Matthews, T. A. Shore and A. Sparks.

As for the coming year, besides the railway station there will be an addition built to the Protestant Hospital, at a cost of $60,000, and a block of new stores on Sparks street to cost about $50,600. Other than these there is not much new work in sight yet.

HAMILTON.

In Hamilton there has been a considerable decrease in the value of the buildings erected. An estimate of the year's operations gives the figures at $293,465, a decrease from 1894 of $113,000. Beyond the new station and freight shed of the Toronto, Hamilton and Buffalo Railway, and the Hunter street tunnel for the same line, there is nothing calling for special mention. The Centenary church erected an addition in the form of a Sunday School building, otherwise operations have been pretty well restricted to residences. Brick is the principal material employed.

Outside the city, however, the Smelting Works Co. have been erecting extensive buildings and plant. The value of these is not included in the above figures, though it was principally Hamilton material and labor that was employed.

The prospect for this year is bright. A new collegiate Institute and school of pedagogy is to be built, which will cost some $60,000 or $70,000.

LONDON.

The year has been a very satisfactory one for architects and builders in the Forest City. No less than 150 buildings have been erected, at a cost of over $420,000. Residences have predominated, but there has also been great activity in church building. Two large Methodist churches have been erected to take the place of two destroyed by fire within a short time of each other. The power house of the Electric Railway Co., with its necessary adjuncts, represent a large outlay.

The following are the principal buildings erected, with their cost and the names of the architects engaged:—Queens' Avenue Methodist church, $100,000, E. Burke, Toronto, and H. C. McBride, London, architects; Dundas Street Methodist church, $50,000, John King, Toronto, architect; St. Matthews Church of England, $10,000, Moore & Henry, architects; Free Library building, $15,000, Herbert Matthews, architect; Y. M. C. A. building, $15,000, Moore & Henry, architects; London Street Railway Co.'s power house, $10,000, American architects; residence for Jos. Smith, $10,000, Herbert Matthews, architect; D. S. Perrin's residence in the country, $10,000, and biscuit factory, $12,000, Geo. Craddock, architect. Knox Presbyterian church, in London south, has also undergone alterations to the extent of $8,000.

Other large works have been completed, such as the two large steel bridges on the London and Port Stanley R. R., built by the Dominion Bridge Co. O. A. Graydon was the engineer. These bridges are 624 ft. long by 69 ft. high and 512 ft. long by 71 ft high respectively, costing together $54,000. Another bridge, by the same company, was placed over Javitt's pond, with a 264 ft. span and having a height of 30 ft. It cost $10,000.

Over a mile of asphalt pavement has been laid on Richmond street, from the G.T.R. station to Ridout st., at a cost of $6,600. The Barber Asphalt Co., of Buffalo, laid it.

The prospect for the coming year is considered good.

KINGSTON.

Very little building was carried on in Kingston during the year, the amount expended not exceeding $70,000, which is less than for the preceding year. Operations in business and public buildings were confined to alterations and repairs, and any residences built were of the cheaper class. Materials and labor commanded lower prices than in 1894. It is a little too early to say what the year 1896 will bring forth, but at present there is no prospect of much activity.

BELLEVILLE.

As anticipated a year ago building has been much more active in this young city than in 1894, nearly double the amount having been expended on new buildings. The structures calling for special mention are St. Andrew's church, to replace that destroyed by fire, at a cost of about $30,000, and an annex to Albert College, representing an outlay of some $20,000. Messrs. Darling, Sproatt & Pearson, of Toronto, were the architects of the former, and Messrs. Geo. M. Miller & Co., of the latter. In addition there have been a number of fine residences built, Mr. Thos. Hanley, architect, having had the oversight of four. The material used was principally brick. Material and labor were about the same in price as in 1894. The total outlay was from $170,000 to $200,000. An electric street railway has been built. The prospect for the coming season's operations is hopeful.

BROCKVILLE.

There has been greater activity in this town than for several years, a spurt having set in in the building of terrace houses renting at from $20 to $30 a month. Several such have been erected. Additions have been built to both the General and St. Vincent R. C. hospitals, at a cost in each case of somewhere about $10,000. A goodly number of small houses were built by workmen for their own accommodation, while at the new asylum, just east of the town, a number of cottages have been completed and occupied. Work has also been commenced on the International bridge, and considerable stonework done on the piers. The outlay for buildings (the asylum and bridge not included) will amount to some $175,000 or $200,000. The Cossitt terrace represents $20,000 and the Publow terrace $23,500. For the former Mr. G. A. Allan was the architect and Messrs. Simpson & Hagarty contractors for all trades except plumbing and heating, which was done by Barsalow & Co.; for the latter Mr. O. E. Liston was architect, with the same contractors, except plumbing and heating, which went to Mr. W. S. Gamble. The prospect for the coming season is promising. A summer hotel is talked of, and an electric street railway is a certainty.

ST. THOMAS.

There has been a falling off in building operations in St. Thomas the past year and operations have been confined pretty much to a good class of brick residences and a few business places. The price of building materials has been a little higher than in 1894, but labor has been about the same. One firm of architects, Messrs. Long & Long, have had work in hand representing an outlay of $57,100, a considerable share of which was, however, outside the city, including a number of churches, and the Industrial Institute at Mencey for the education of Indians, which cost $30,000. The prospect for the coming year is only fair.

STRATFORD.

About $85,000 has been expended in Stratford, which includes $15,000 spent on the restoration of the post office. The balance was chiefly on residences of a cheap class, largely brick veneer, and the total shows a falling off of $20,000. Work being scarce, labor could be had at a lower rate than formerly.

CHATHAM.

Chatham having reached the dignity of a city the people have felt prompted to put on metropolitan airs, and building operations took on a briskness accordingly, the record showing a considerable excess over 1894. Probably $150,000 will approximate the outlay. The principal buildings were a fanning mill factory, costing $25,000, T. J. Rutley, architect, Richard & Co., contractors; Presbyterian church, $8,000, Jas. L. Wilson, architect; Methodist church, brick veneered, $1,800; and brick houses costing from $5,000 down. Both brick and lumber were cheaper. Wages were about the same.

SARNIA.

Sarnia erected a general hospital of brick at a cost of $25,000, of which Mr. H. G. Phillips was architect. Other operations were confined almost entirely to a cheap class of residences, largely of wood, and $35,000 will probably cover the cost of buildings erected in the town during the season.

COLLINGWOOD.

A marine hospital costing $5,000, a Presbyterian church, $5,600, the Globe hotel $14,000, and additions to the Collingwood Meat Co.'s buildings, $4,000, help to swell the value of building operations in this town. The outlay has been some $20,000 more than in 1894, and the total will not be far from $88,000, the balance being principally residences. Brick was the principal material used. Skilled labor was higher. For the hospital Mr. Fred T. Hodgson was architect and Peterman & Sons contractors; for the church, Gregg & Gregg, Toronto, architects, Bryan Manufacturing Co., contractors; for the hotel, F. T. Hodgson, architect, and Wilson Bros., contractors; for the Meat Co.'s buildings, John Wilson, architect, and the Bryan Mfg. Co., contractors. Next season it can hardly be expected that so many new buildings will be erected.

QUEBEC.

The ancient capital, respecting which a falling off was noted in last year's review, has experienced a further retrograde movement, which does not augur well for the future of this interesting old city. About $350,000 has been expended, of which $125,000

was spent on a new city hall, and a considerable proportion of the balance on the Church of the Patronage. About 40 per cent., 35 per cent., and 15 per cent. respectively—will indicate the proportions of the total spent upon public, business, and residential properties. The material employed was about one-half stone, and one-fourth each brick and wood. Brick has been about 20 per cent. lower in price, stone and wood about the same. Bricklayers' wages were about 50 cents per day less, joiners' 20 cents less, and laborers' about the same. For the city hall Messrs. Tanguay & Vallee were the architects, and Messrs. Gingras, Gurcherean, Kane & Picard, contractors. For the church, Mr. Berlinguet was the architect and Mr. Paul Breton contractor.

OTHER TOWNS.

Other towns from which reports have reached us do not seem to have experienced much activity. Buildings have been erected in Galt to the value of about $30,000; Owen Sound, $20,000; Guelph, $120,000; Brantford, $150,000; Woodstock, $100,000; Berlin, $117,000. In Guelph five miles of electric street railway and five miles of cement sidewalk (making a total of 12 miles) have been built, and Woodstock rejoices in a new market building. Operations in the towns consisted principally in the erection of dwellings, the condition of business not warranting much outlay for premises to be used for purposes of trade and commerce.

MARITIME PROVINCES.

During the last eighteen or twenty years building operations have been very brisk in the principal parts of the lower provinces, particularly in the smaller towns and villages of Nova Scotia and New Brunswick. These include buildings for various purposes, churches, factories, mills, hotels, colleges, schools, stores, post offices, public halls and dwellings, the greater number, of course, being of the latter class.

Travelling through the provinces one cannot help wondering at the lack of taste displayed in the erection and locating of recently built dwellings. Few indeed, comparatively speaking, possess any of those pleasing architectural features such as are seen on houses designed by skilful architects.

Occasionally an architect's services are called into requisition in designing a dwelling for the country or smaller towns, and if the owner gives him a chance at all to spread himself in his efforts to produce a good design, the result is usually satisfactory to the architect, client and all who chance to see the building.

Unfortunately, however, when people outside the cities contemplate the erection of dwellings, the usual course is to consult a carpenter, get his ideas and apply a few of their own, adopt some features from one neighbor's house and some from others, regardless of harmony and architecture. In some cases the patent medicine system is adopted and buildings are erected from plans found in some American publication. In either case the owner usually finds at the end that he has made a mistake and got an unsatisfactory house.

When an architect is employed the owner invariably makes the amount to be expended so limited and requires so much house for the amount, that there is little margin for ornamentation.

Building is more expensive in the lower provinces than in Quebec or Ontario. Handsome brick and stone residences have been built in the latter provinces for less money than an ordinary frame house of similar dimensions costs in the former. This is owing to the lack of facilities in the shape of manufactories in the lower provinces, and to some extent to the scarcity of good local woods for finish purposes, spruce being about the only stock of any importance obtainable. Good pine is a thing of the past, and birch, maple, oak and ash are not to be found in trees of sufficient size to make good finish stock.

Many builders in the country towns, and some in Halifax, import their pine doors, mouldings and other finish, from Ontario factories.

In the cities there is a lack of good general system among builders in carrying on their operations. They are slow to adopt new and improved methods to facilitate works. Still owners are inclined to stand by the old hands and very wary about letting work to outsiders.

Building in the lower provinces is done almost entirely by contract, the several trades being let to one party, who sublets all but his own trade, and is responsible to the owner for the whole.

ST. JOHN, N. B.

The number of building permits issued in St. John for the year was 82, being about one-third more than in 1894, and the outlay on the same $178,475. This does not include Carleton, on the opposite side of the river, which is a separate municipality. Including that suburb probably $250,000 has been expended. The only buildings calling for special mention are a Baptist church, cost, $18,000, H. H. Mott, architect, W. L. Prince and Robt. Maxwell, contractors; the Aberdeen Schoolhouse, cost, $20,000, R. Dunn, architect, B. Moony & Sons, contractors; Wygoody buildings, store and warehouse, $20,000, H. H. Mott, architect, Charles F. Tilley, contractor. Mr. G. Ernest Fairweather has built an addition to the Royal hotel, and three saw mills have been rebuilt, and a corn mill. Other operations were principally in the way of two-storey wooden dwellings. Twelve buildings of brick and stone cost $93,050, and seventy of wood cost $85,425. Material and wages stood at about the same figures as last year.

HALIFAX, N. S.

The capital of Nova Scotia reports a considerable increase in the total value of buildings erected, but a larger number of cheap dwellings. The details are, dwellings 97—brick 4, wood 93; business erections 50—brick 6, wood 44; public buildings 3—brick 1, wood 2. The value of these structures is about $600,000. The most important building for which a permit has been granted is the drill shed, a brick and stone building estimated to cost $200,000. Other buildings calling for special mention are: Deaf and Dumb Institute, $50,000, brick, J. C. Dumaresq, architect, S. A. Marshall, contractor; Electric Railway Co., car building, $25,000, brick—Rhodes, Curry & Co., contractors; I. C. R. freight house, $30,000, brick, R. C. Donald, contractor; Peoples store, $15,000, brick, J. C. Dumaresq, architect, S. A. Marshall, contractor. Brick and iron have been slightly cheaper in price, other materials about the same. Wages have remained about as in 1894, except that the demand for carpenters and labourers being great there was a slight advance. New sewers, new streets and pipe laying for the new gas company have made a demand for labour, and next season a new drill hall and new gas works will keep up the record for building.

WINNIPEG, MAN.

About $650,000 will represent the building done in Winnipeg the past season, $200,000 of which was expended in putting stone foundations under old buildings, with the necessary plumbing, heating and drains. The speculative building which we condemned in last year's review has been well eliminated, and a remarkable degree of caution exercised. This has resulted in keener competition among contractors, leading to low prices and less profit. Building materials have been a shade under former prices, skilled labour has stood at the old prices, but unskilled has been a little less. Three new school-houses have been built and Wesley college completed. A few good business blocks have been erected, and a considerable number of houses, but not so many as the previous year. The Dufferin school house cost $26,000 and the Argyle $25,000. Mr. C. H. Wheeler was architect of both. The Mulvey school-house represents $23,000. Mr. Geo. Browne was architect. The expenditure on Wesley College was $35,000. Peters and Brown were its architects. Mr. Wheeler also supervised the erection of the Campbell block on Main street, cost $17,000, and a fine red brick and stone house for Mr. Hugh John Macdonald, costing $11,000. Mr. Browne was the architect of a Masonic Temple costing $16,000. Mr. H. McEwen had the Christie block in charge, costing $17,000. Mr. Peters planned Ashdown warehouse, costing $40,000, and Mr. Griffiths a warehouse for Mr. Ryan costing $10,000. Wood is still the predominating material in the city and nearly all the dwellings are built of that material, on stone foundations.

The outlook for the coming season is uncertain. Though there has been an immense crop in Manitoba, prices are low, and there is not much encouragement to launch out into enterprises involving considerable expenditures.

OTHER NORTH WEST TOWNS.

At Brandon the season's building represents some $20,000; at Minnedosa $32,000; at Carberry $22,000, and at south Edmonton, a four year old town, $75,000. The most important building at the latter is an oatmeal mill of Brackman & Ker.

VANCOUVER, B. C.

This has been an exceedingly dull year in British Columbia, except perhaps in some of the mining centres, and in common with the rest of the country the cities have not progressed to any marked degree. Building operations have been backward and there has been a great scarcity of employment. Vancouver, the most progressive city of the province, can show new buildings to the amount of $100,000, and these are chiefly small cheap dwellings of a speculative class. Any business structures are of most similar class, and the only public building reported is a small wooden school house. Both materials and wages are down in price, and the trade generally is much depressed. There are too many men to do the work required. The only building of any account in prospect is a large hotel for Messrs. Crean & Thomas, of which Mr. Wm. Blackmore is the architect.

NEW WESTMINSTER.

What has been said of Vancouver is also true of New Westminster. Only two buildings of any consequence have been erected, a drill hall of wood, costing about $7,000, and additions to the provincial lunatic asylum, principally for a doctor's residence, costing $6,000.

VICTORIA, B.C.

In Victoria, though operations on business and residential properties have been restricted as in other British Columbia towns, a large sum has been expended on government buildings. Work has been pushed forward on the new parliament and departmental buildings, which, when completed, will represent an expenditure of not far from a million dollars. They are of handsome architectural design and will be a credit to this young province. In fact they are quite beyond present requirements, but the government has faith in the future, and has built with an eye to a large increase in public business in the time to come. The work was executed from the plans of Mr. F. M. Rattenbury. The contractors were: masons, McGregor & Jeeves; joiners, Bishop & Sherborne; plasterer, R. Drake; iron work, Albion Iron Works; coppersmiths, Perry & Turner; plumber, R. J. Nott; heating, Bennett & Wright Co.; painter, E. Spillman.

The new post office, which is also under way, will when completed be a handsome building. It is being erected under the superintendence of the government architect, and will cost about $175,000. The contractors are Messrs. Elford & Smith. These two works have given employment to a large force of men, who would otherwise have found it difficult to obtain work. Besides the public buildings mentioned above, about fifty small houses have been erected. Considerable alterations to existing buildings have also been made. Wood and stone have been used to the greatest extent, and the price of materials has been about 10 per cent. below the previous year.

In other British Columbia towns there has been great stagnation, any buildings erected having been of the cheaper class.

POINTS FOR YOUNG CONTRACTORS.

By David G. Baxter.

The lids are ivy, grapes in cluster lurk
Beneath the carving of the curious work.
—Dryden.

WHAT apprentice boy in the building trades, let him belong to what line he may, if he possesses one grain of inherent ambition, does not look forward to the dim and distant future with a burning desire that he, like his principal, shall be a contractor, an employer of men, a purchaser of material, a director of works; yet little seems he to dream of the hard study, the unremitting work, anxiety and worry, the rough unsympathetic buffeting he must pass through before he obtains his final settlement on his first job, ner that the harder he studies in the following lines, the more he is guided by the following facts, the more satisfactory this settlement will be, the more gratifying all future settlements shall be found.

Every effort is the result of some cause. A man decides to take contracts, to become a contractor—there must be some cause leading this man's brain into this groove and producing from him a contractor. Will he succeed or will he not? It all depends upon his ability, his resources, his education, yet affected and modified to a great extent by that cause, that chain of circumstances may we call it, that led him into this branch of human endeavor. This man would not go into the dry goods or into the grocery business because he knows that he does not understand either of them, and that he would naturally be unsuccessful. For a like reason he should not undertake to set up as a contractor unless he understands fully and completely that line of contracting he intends to take up. Throughout the country we find men without any previous preparation taking or endeavoring to take contracts because they are out of work through hard or dull times affecting their former contractor employers, or because they have become dyspeptically dissatisfied with things in general and with ordinary hard work in particular. These men float aimlessly around figuring on proposed jobs, and having no previous reputation, are forced to take what work they can manage to get at ruinously low prices, much to the detriment of good work and to the injury of reliable, established contractors. These men are to-day working day work and to-morrow contract work; we cannot call them "contractors," but must designate them "jobbers," and as such dismiss them from consideration.

There is another class who, with inborn wish to succeed and to make the world brighter and better, before commencing business study for years their work in its every phase, its every form and give it—their chosen life work—the full consideration and deliberation that it deserves; these, when they do start out, instil confidence, and in confidence get better prices and more satisfactory settlements than the men who, without previous preparation, assume to take contracts because they were dissatisfied workmen.

It is to this class of ambitious men that these words are addressed, especially to those located in places outside the larger centres of civilization, when the question of what or what not to do, as preparatory for the future, is often a very serious one with many young men in the building trades, in whose breasts is firmly implanted a desire to excel. I do not want to be interpreted as saying that a building mechanic suddenly thrown out of work should do nothing till some contractor can give him work—that he must not take work direct from the layman himself—far from it; let him do anything and everything in his power to make an honest dollar, but I do most strongly dissuade him from thinking of becoming a permanent contractor or firm, himself as principal, taking anything except small repairs and such like, unless he be thoroughly equipped for the work. This for his own good. In regard to the omnipresent genius of dissatisfaction, the sooner he taketh his departure for the sunny slopes where the woodbine twineth, the better for all.

A contractor to be successful in turning out good work and in making money, must possess a great amount of practical ability; he must thoroughly understand, practically, every branch of his work in its ever-changing phases; besides he must have acquired a fair smattering of the theoretical side, to understand, if not to calculate, the laws of strength and stability. If he be a bricklayer he must have an idea of the principles of foundations, arches, piers, buttresses, etc., besides a rough knowledge of the chemical and physical properties of limes, cements and other materials. If he be a carpenter, a knowledge of the governing principles of roof and other trusses, beams, columns, etc., is indispensable, and an intimacy with the nature of woods is also essential. If he be a plumber a familiarity with sanitary science and an insight into the laws of traps, vents, flow of water and a hundred and one other points is imperative; and so on through every trade; in short we are brought face to face with the survival of the fittest ultimatum—that to attain to full success a contractor must understand all about his particular line of work that he can learn by watchful experience and by incessant unremitting study during his spare moments.

It may be said that it is impossible for a contractor to study any theory because his education is as a rule such that it does not fit him to understand formulas and technical terms, and even could he elucidate them, he as a rule cannot spare the time. All that can be said in reply is, that if he has the slightest desire to get to the top of the ladder he will find the time or make it, and he will repair or replenish his education up to the point which is necessary to understand the said formulas and technical terms. This can be no very difficult task, for in the market there are hundreds of plain, simple, reliable books on each trade, easily gotten hold of and as easily understood, teaching the computation of strains and how to meet them, the guiding rules, etc., in such simple form that the most ordinary education can fully grasp them. Then again he will contribute greatly to his own interests by subscribing to a couple of trade journals devoted to his own line and to at least one architectural paper. These will keep him in touch with new methods and practices being perfected or brought out and with newly introduced materials, tools and other mechanical devices. In addition, he should be the possessor of a library of trade catalogues, which he should study carefully and repeatedly. Technical journals supplemented by trade catalogues are without doubt the very best educative mediums that a contractor or mechanic can possess. The more knowledge a contractor can acquire the more confidence he naturally will receive from his employees, and this knowledge he should try as far as possible to transmit to them; he should endeavor to make them thinkers and students as well as workers.

A thorough acquaintance with business methods is imperative. Book-keeping, banking, exchange, correspondence, etc., should be to the contractor familiarities. This knowledge can be easily acquired if both eyes be kept open and a little assistance be sought from some qualified friend, or a short time might be profitably spent in some good business college, no more than merely enough to acquire simply a rough proficiency in business practices; more would only be a waste of time. On this score of business methods the embryo contractor need suffer no uneasiness, for these points are so very easily acquired and from so many sources.

The acquisition of a reliable unfailing judgment of human nature is of inestimable advantage. The power to judge character and motive in employer or employee is a very beneficial adjunct to success; it teaches the contractor the various whims and caprices of his men and just how to handle each individual one so as to get from him the greatest amount of perfect work in the shortest possible time. This faculty comes quite naturally to some, but it can be easily acquired by all; any rule for its study other than "watch faces" would be hard to give.

Interpretation of plans and a knowledge of the customary terms used in specifications is of course an absolute necessity. Let our embryo contractor look over and study every plan he can possibly lay his fingers on, and a friendship formed with some architect's clerk will be a great benefit in the way of explanations of lining and coloring, use of scales, rules for estimating, and many other valuable points.

Then there is what may be called the legal aspect. An acquaintance with the law relating to contracts, liens, garnishes, etc., will save a great deal of troublesome uncertainty and worry. A wonderful amount of information on this point may be obtained from reading the various technical journals. That this is a point of great moment to contractors as well as to architects seems to be recognized by these papers, which are giving a good deal of attention to it by publishing particulars in general, and judgments in building cases. Take an interest in and carefully follow all trials of building cases that you possibly can, especially those in your own locality, and note the legal points brought out by counsel and judge.

It is, of course necessary before beginning business to have a certain amount of cash capital, at least enough to carry through the first few jobs till returns begin to come in, and in no case should the new beginner allow himself to be seduced into taking more work than his capital will warrant, no matter how glittering the prospect, no matter how sure the success may appear. His ability and willingness from the start to pay promptly for materials will engender confidence in, and reliance on him by the supply dealers, and when he comes to take larger contracts it will be pleasantly surprising how his custom will be sought and how much better the bargains he can make than can his slip-shod brother contractor who has no such reputation.

Estimating correctly is a very vital point with any contractor. A faulty estimate may mean a very heavy loss or it may be the means of throwing him out of the work. Estimate carefully, considering every point in the plans and specifications; miss nothing. Low estimates are often caused by an improper conception of what is to be done, a loose consideration of the values of different features; get the quantities and qualities correct and the values as low as possible, and if this does not secure the work let the other fellow have it and welcome. Never sign a contract before again considering the amount and class of work to be done and materials to be supplied, and should at any time some unscrupulous proprietor request that the job be taken at a certain reduction from the tendered price, don't jump it! Consider it first; don't take work for the sake of work. When figuring make out the quantities in tabulated form, entering every article, every item with its estimated value opposite, all being done in a regular form—each proposed job separately. Whether the job be secured or not keep all of these estimates in some permanent shape, for they will be a record of the past and a valuable guide for the future. While the work is progressing for each building separately, keep track of every article sent to the ground, every article returned, and a correct account of all labor spent on the work; enter the cost opposite each item. This record will fill a two-fold purpose—that of showing the relation between estimated and actual cost, being the loss or gain on the whole or on each item, and also teaching a most valuable lesson for future tendering.

Study the markets, the rise and fall in prices of materials not only in your own line but generally in all other lines, and particularly see that the technical journals you subscribe to give you the regular market quotations up to date, of course discounts and freight rates change the face of matters considerably, but the prices quoted will always be a safe criterion by which to follow the everchanging tide of values. These quotations are customarily given for the largest markets and which are always specific-

ally designated. Most certainly when it comes down to buying, correspondence must be resorted to. By the way, let me add that another benefit of the library of technical journals is that they tell in their advertising pages the names and addresses of the principal dealers in each line; this fact alone is worth the subscription price to any contractor.

In regard to extra work a little advice might not be out of place. When a proprietor or his agent, who is as a rule the architect, suggests changes, additions or deductions, at once look up the specifications and see exactly how the matter stands and do not make such deviation from the amount or class of work contracted for until you have first amicably adjusted with the proprietor the price that is to be added to or deducted from the contract amount; then you will know how you stand and the proprietor will know how he stands, and there will be saved all the untold squabbles and dissatisfactions over the "extras" at the final settlement.

A contractor has duties to his employer as well as to himself; this he should always bear in mind. The better he can satisfy his employer the better it will be for his reputation now and to come; one dissatisfied proprietor will by far outdo the good that ten satisfied ones can do him, and he will usually try to do it, too. When I advise trying your level best to satisfy the proprietor, I do not say to exceed the specifications, for that is uncalled for, but success can only be obtained by conscientiously filling them to the last letter.

The relation a new beginner bears to those previously established in his line in the same locality is at first on the part of the old heads often one of suspicion. This is human nature. To speculate on his qualifications, his resources, his everything, is only natural in those to whom he is now to be a rival. Barriers may be thrown in his way—but what of this, fair, square dealing will outlive all. Keep a stiff upper lip; be honest by all and fear none. This procedure if conscientiously lived up to will give to any man a certain noble personality, a certain impress of absolute reliability that all the storms of adversity or enmity cannot shake, that will stamp that man as a man among men, and success is assured.

ILLUSTRATIONS.

RESIDENCE AT LONDON, ONT. HERBERT MATTHEWS, ARCHITECT.

CATHEDRAL-CHURCH OF WELLS, SOMERSETSHIRE, ENGLAND, FROM A DRAWING BY MR. ERNEST WILBY.

Wells Cathedral, 1148-1407, is one of the most interesting of English Cathedrals, and will merit a visit by the travelling architect or student. The view presented shows the easterly end as seen from the Bishop's garden.

MARKET BUILDING AT WINNIPEG, MAN. GEORGE BROWNE, ARCHITECT.

The building is built of stone and local buff brick. The exterior walls above ground line are hollow, pointed and painted on the interior side; no plaster. The roof over centre portion has a clear span without the beams or rods; cost $24,000.

"C. A. & B." COMPETITION FOR A JEWELRY STORE DESIGN SUBMITTED BY "ROMANESQUE" AWARDED FIRST POSITION.

The whole of the front of the first storey, the columns, sills and lintels of first, second, third and fourth floors, the arches, spandrils and string course above third floor windows, the panelling under cornice and the large brackets at ends of cornice to be of the best quality of Cleveland blue stone. The rest of the front wall, excepting cornice, to be faced with the best selected buff bricks of an even tone and backed with good ordinary brickwork.

"C. A. & B." COMPETITION FOR A RETAIL JEWELRY STORE. DESIGN SUBMITTED BY "PENNY" AWARDED SECOND POSITION.

Foundations are to be built of hard gray or sewer brick on footings of stone. All walls except the front are to be of good white brick. The front above the ground floor is to be built of Don Valley buff pressed brick. The ground front is to be of Berea stone, as also are all sills, capping, strings, cornices, pillars, and panels. All the partitions above the ground floor are to be 4½" porous terra cotta.

THE JAMIESON BUILDING, TORONTO.—CURRY, BAKER & CO., ARCHITECTS.

As the land upon which this building is erected is possibly the most valuable in the city of Toronto, it was absolutely necessary to make the most of the site. Every inch of frontage on Yonge street has a value of $200.00, and it was consequently imperative that none of it should be wasted. The glass line of the store windows is within 3½ inches of the face line of building with the supporting columns inside of same. The result has been satisfactory, for although the ground floor of the building is almost all glass it has not the appearance of standing upon spars, which is characteristic of many buildings with large plate glass surfaces. There is an entrance from Yonge street and one from Queen street, the balance of the frontage being devoted to showing goods, thus forming a large and continuous store window extending from entrance to entrance. Along the inside walls there are two galleries about 13 feet wide, through which the elevator and staricase are carried. The gallery at the west end will be used for office, that on the north side for showing goods. The available space on the store floor is very largely increased by means of the galleries. The basement will be used for selling goods, and is exceedingly well lighted. Much thought was devoted to the lighting of the basement, and the result is most satisfactory. Three of the upper floors will be devoted to thesale of goods, while the top floor will be used for manufacturing purposes. The upper floor is lighted by three very large skylights. The floors throughout are carried on steel beams supported by cast iron columns.

The building is not fireproofed, but every care has been taken to prevent the spread of fire. There is no strapping upon any of the walls, and the ceilings are plastered upon metal lath. A stand pipe is run up through the building to the roof with hose on every floor. Ohio free stone is used in the ground storey, including the corner, and stone and brick in the first storey. The balance is built with a very light buff pressed brick with terra cotta arches. The cornice is of galvanized iron painted to harmonize with the brick.

"STOKOSAY CASTLE."

The view given in this number of this interesting old mansion shows the North Tower from the church-yard looking across the moat. On the left is seen the Tudor "black and white" gatehouse, of which a drawing with details and a general description was published in this paper last March. At the northern end of the great hall a short flight of steps leads downwards into an apartment which is probably the most ancient part of the buildings; the very narrow loop holes show that it was intended for defence. In a projection of this chamber is a well, 150 ft. deep, which was nearly filled up, but has recently been cleaned out. A boar and deer skull and a pair of roebuck's horns only were found. An original staircase of solid oak baulks, cut through diagonally, leads from the hall to the first and top floors. On the first floor are two apartments which are named the priest's rooms. The innermost room, probably used as an oratory, is laid with a number of tiles of good design, several the device of a centaur, an archer and coats of arms. A projection in the angle contains a small recess. Little change has taken place except the insertion of an ogee window, which will be noticed on the drawing.

The upper room is of very irregular shape a well lighted apartment 25 ft. x 30 ft. This half timber structure was probably put on at the same time that the gatehouse was erected, and replaced the original parapets of the tower. This room has probably been divided by light partitions. There is a fine example of an early English fireplace, with side pillars, down which runs a rib. A wooden frame resting on corbels which once supported a wooden hood still remain. Though the upper part is gone, the line is defined by the groove in the wall.

The floor of this room partly rests on brackets projecting from the walls, and is thus of greater size than the lower structure.

The roof principals are very irregular. The ridge is on the twist and anything but level, but they got over these slight difficulties by giving gentle sweeps to the tiling. The basement walls are very thick, and it will be seen they have considerable batter.

The great hall is lighted by three large windows on either side filled with early English tracery, grooved for shutters, and in the lower divisions holes sunk in the stone to admit iron bars. The far gable seen in the sketch is the solar with the battlements of the south tower above.

This is not the general view, which, together with measured drawings, I hope to give at a future date and with a fuller description. EDWARD SWALES.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—NO. 2. FEBRUARY, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

Proposed Amendments to the O. A. A. Act.

To Mr. Frank Darling, the retiring president of the O. A. A., is due the credit of having delivered at the opening of the recent annual convention, a highly practical address. It may safely be said that to the majority of the members of the Association, who recognize in Mr. Darling the possessor of high artistic attainments, the intensely practical character of his remarks came as a complete surprise. There was no disappointment on this score, however, as every one felt that the address was full of valuable suggestion and sound logic, befitting the occasion. Mr. Darling largely devoted his remarks to showing the reasonableness of the amendments which the Association are seeking to have made to the Ontario Architects' Act. He undoubtedly presents a strong case, and one which clearly has justice as its foundation. We desire to emphasize two or three points which the members of the Legislature and others interested should keep clearly in mind. 1st. The desired amendments to the Architects' Act would not prevent any person from preparing plans for and carrying out the construction of buildings as at present. The only restriction would be in the use of the title "Architect." No unqualified person would be permitted to call himself an "Architect," although he might, under a different title, perform the work of an architect. This restriction is desired in order that those who invest their capital in new buildings may know who are qualified to design and erect the same in a manner that will not involve risk of financial loss to the owner and injury to health or loss of life to the occupants. It is compulsory on the surveyor who lays out the site of a new building that he shall give proof of his qualifications; how much greater the necessity for such proof in the case of the man into whose hands are entrusted capital, health, and even life itself? 2nd. As every person at present practising architecture in Canada would be given three months in which to register under the Act, without being required to give proof of qualification, no injury or injustice could result to them. 3rd. Those who are seeking to have the Act amended have nothing in view beyond a desire to safeguard the public interest, and elevate the standard of architectural practice in this country. As the benefits of the legislation would not be felt to any extent for twenty-five or thirty years, it is clear that the practising architects of the present day can expect to derive no personal advantage therefrom. 4th The School of Architecture established by the government in connection with the School of Practical Science,

Toronto, in recognition of the need for the more thorough education of architectural students, must fail of its object, unless it is made compulsory that students shall pass qualifying examinations. In view of these and other equally good reasons which could be advanced, it is hoped that the amendments to the Ontario Architects' Act, which have been petitioned for, will be granted at the present session of the Legislature.

The O. A. A. Convention.

THERE was less business than usual transacted at the Annual Convention of the Ontario Association of Architects, but the papers were rather more interesting than usual, and, what is more important than all, there was more evidence of fellowship among the members attending the meetings. In particular the portion of the programme devoted to criticism of each other's current work, exhibited by means of the stereopticon, was definite and instructive, and both given and received in a frank and friendly spirit. It is this spirit which is one of the best products of the Association as far as concerns the architects. Inventive workmen, such as artists and architects, require constant association and interchange of ideas to keep up the germinating warmth of thought that must be at the back of progress, without which Art is dead. Until the Association was formed the architects of Ontario, even in the cities, worked alone. It would be hard to return now to the old state of affairs; nor would it be easy to estimate how much architecture in Ontario will owe to the Association for this one gain only. Any comment upon the recent convention would be incomplete without a reference to the liberal assistance to the Association of all connected with the School of Practical Science, beginning with the Minister of Education. Mr. Ross has always shown himself to be a Minister of Education in the widest sense of the term, and the formal vote of thanks to him at the close of each convention is offered not only in return for his permission to use a room of the School for that convention; but is at the bottom an acknowledgement of his promotion or countenance of many ways in which the School has extended its assistance to architects as well as to students of architecture. Professor Galbraith, the principal of the School, not only watches over the association of his teaching staff with the practising body, but gives valuable time in acting as Chairman of the Board of Examiners of the Association, and organizing a scientific method of examination. Mr. Wright, the Lecturer in Architecture, is the familiar friend of the Association, and his unwearying energy and dauntless enthusiasm have done more for it than a mere enumeration of his services would express. The annual conventions in particular owe much not only to his assistance, but to his suggestions. A distinguishing feature of the conventions is the facility of illustration afforded by the electric light stereopticon of the School and the valuable collection of photographic slides of architectural subjects made by Mr. Wright and his assistant, Mr. Keele, for the use of the architectural department of the School. Some of the photographs were taken by Mr. Keele during a visit to England in the last vacation, and are valuable not only as excellent protographs but as having a subject matter chosen by an instructor in architecture. It seems to us not only a good thing for the Association to work thus in harmony with the School, but it must also be a good thing for the staff of the School. There is danger to all professional work in its withdrawal from active life and dealing with theoretical matters only. The college professor too often becomes dry if not inactive in the course of time. To this tendency an association such as now exists between the instructors at the School of Practical Science and the practical part of the profession is a wholesome corrective.

BUILDERS' EXCHANGE.

THE annual meeting of the Toronto Builders' Exchange was held on Monday, Jan. 20th, at their rooms, No. 8 Victoria street. The following members were present: Messrs. Oakley & Holmes, James Crang, Wm. Booth, John Vick, D. Williams, J. Bedford, H. Lucas, T. Cannon & Son, John C. Goddard, William Christie, John Connolly, A. Burnett, Wm. Pears, Jas. Pears, Wickett Bros., Wm. Tasker, John Maloney, Henry & Bottomley, J. J. Blain, Thos. Murray, James Isaac, Thomson Bros., Wm. McGuire, Geo. Wright, J. Knox, John Aldridge, John M. Gander, R. Chalkley, Wm. Stewart, Wm. Harris.

The election of officers for 1896 resulted as follows: President, John Aldridge; first vice-president, T. Cannon, jr.; second vice-president, John Vick; treasurer, David Williams.

The following directors were elected: William Booth, John Wickett, James Crang, John M. Gander, George Henry. The auditors are Messrs. Fred Holmes and George Clay.

The reports of the directors and auditors were presented and adopted, and votes of thanks tendered to the retiring officers. It was resolved to hold the usual annual excursion next summer, a committee being appointed to make the necessary arrangements.

LEGAL.

A CASE of interest to architects came before Judge Morson at Toronto recently, in which Mr. Hynes sued the Roman Catholic Separate School Board for $60, commission for plans furnished for a school building on Earl street. It appears Mr. Hynes was employed to draw plans for a four-roomed building, and that he submitted them when ready to the Sites and Buildings Committee, but that they were dissatisfied. He explained that he could do no better, as the appropriation was limited to $4,500. He understood that he was then authorized to make sketches for a more expensive building, and he accordingly did so for one to cost $6,000, which were submitted to the Archbishop for his approval, and he asked 1 per cent., the regular commission on this amount. After hearing the evidence Judge Morson held that the Building Committee had not authorized the second plans, and as Mr. Hynes had been paid $112.50 for the first plans, judgment was given in favor of the Board.

BRITISH COLUMBIA PARLIAMENT BUILDINGS.

THE exterior stone work of the main portion of the new parliament buildings at Victoria, B. C., has been completed, the last stone having been laid with great eclat a few weeks ago. The contractors, Messrs. McGregor and Jeeves, invited the members of the government and some others to be present. The Union Jack was hoisted and congratulatory speeches made. Both the architect and contractors are commended for the energy displayed and the character of the work. The last stone was laid on the dome, which towers eleven feet. Above it will be a copper covering fifty two feet high.

Among the new industries which appear to have come very rapidly to the front is The Mica Boiler Covering Co. They have recently completed covering all the steam pipes in the Simpson Departmental Store, Toronto, and have also in hand large contracts for the Ontario Government. Last week they were awarded the contract for steam pipe covering for the Halifax Street Ry. Co., besides obtaining considerable orders in Montreal, and in consequence are compelled to run a night shift to keep pace with their orders.

ONTARIO ASSOCIATION OF ARCHITECTS.

PROCEEDINGS OF THE FIFTH ANNUAL CONVENTION.

THE Fifth Annual Convention of the Ontario Association of Architects, was held in the School of Practical Science, Toronto, on January 14th and 15th.

The President, Mr. Darling, having called the Convention to order at 2 p.m., the Registrar read the minutes of the last Annual Meeting, which on motion duly seconded, were confirmed and signed by the President.

PRESIDENT'S ADDRESS.

The President then read his annual address, as follows:—

It is with pleasure, gentlemen, I welcome you to the fifth annual convention of the Ontario Association of Architects. The past year has not been greatly fraught with matters either of great importance or of much interest to the welfare of this Association.

We have had a quiet year, and I cannot, I am afraid, bring before you anything either very fresh or very novel, as it is my intention to deal almost entirely with the question of legislation.

We are, as yet, but a young institution, struggling for recognition and a livelihood; the latter I feel assured of, if the former can be managed, and managed it must be, and can be, if only we will all do our duty—each of us and all of us.

We are nearer the goal of our hopes now, I firmly believe, than we have yet been, but the prize will not be won without a strong and desperate effort. It is the last spurt in any struggle which requires the greatest exertion and determination in order to achieve victory.

We have it in us to win if we but choose to put forth all our strength. It behooves us, therefore, to make up our minds with grim determination to struggle and fight to the last. There is no need to despair. It wants nothing but a steady, persistent and united effort, and the battle will be ours.

Talking it over, however, between ourselves, in our offices, when we happen to meet in the streets or elsewhere, or reading papers and making speeches in yearly conventions, will not bring about the results desired. I wish it would. It's easy. Talk is cheap and there is plenty of it, but unfortunately it is work that is wanted—not talk—steady, persistent work.

Whenever you can get hold of a member of the Legislature, see that do not neglect the opportunity, but seize the chance, and explain to him as clearly and definitely as you can what it is we are asking for, remove his apprehensions, which you will find are many, and do all in your power to make him understand the matter properly.

It has been found by those members of the Association who have done some work about the Legislative Buildings, in the way of interviewing members, that the greatest opposition to the Act arises either from ignorance, ndifference, or from very serious misapprehension of our intentions. It was found, also, that in the great majority of cases, after our views had been clearly set forth and explained, that the opposition was removed or at any rate, very greatly lessened.

I am safe, I think, in saying that the work which has been done for the last few years in making the members of the Legislature familiar with our aims, seems to be gradually bringing about a favorable feeling on our behalf. Neither on the part of Reformers, Conservatives or Patrons do we meet with any definite opposition. Such as does exist is individual, and does not represent the united action of any party. It does not, indeed, appear to be regarded by anyone as being a party measure in any sense.

The Government refuse to introduce the Bill as a measure of their own, but that, we have reason to believe, is from motives of policy, and not because they have any objection to the Bill itself. Mr. Haycock, the leader of the Patron party, was most kind, showed much interest in the matter, and was extremely desirous of being thoroughly informed on the subject, and in the end expressed himself as having no objection to the Act as amended. Mr. Howland, also, gave us much valuable assistance, and very kindly took charge of the matter in the House.

After consultation with him, Mr. Haycock and others, the Council came to the conclusion that, in order to remove as far as possible any chances of defeat, and to bring the provisions of the Act into harmony with the expressed wishes of various members of the Legislature with whom the matter had been at different times discussed, it would be wiser that the fixing of the amounts of the various fees should be left to the decision of the Lieut.-Governor-in-Council, and not in the hands of the Council of the Association. It is presumed, of course, that suggestions as to the amounts of the various fees will be permitted to be made by the Council of the Association, the Government only interfering if, in their judgment, the amounts appear excessive. We need fear no difficulty, however, on this score, if we prove to the Government that the fees are such only as are necessary to allow the Council to properly carry on the work of the Association.

It is really difficult to see what objection can be urged against the Bill in the shape it now is.

Practically all we ask for is—that the Government shall take some steps to assist us in raising the standard of education which it will be necessary for persons to possess who in the future desire to assume the title of "Architect."

It has resolved itself into an educational matter pure and simple, and not, as it was at one time feared by some people, a sort of scheme by which we could make the practice of Architecture what is called a "close profession."

The Act does not preclude anyone either now, or in the future, from carrying on, as at present, the whole business of an Architect. A man will be able to make plans and sell them, design houses and build them, or do anything else he wishes in the way of ordinary architectural practice. He may charge for his services exactly as he does now, five per cent., or less, or more as he himself may deem such services to be worth. He will have the same facilities for collecting these fees (in the courts if necessary) as he at present enjoys—the only difference being that he will not be able to take or use the title "Architect" in any way or shape whatever. He may call himself by any other name he chooses, and may designate his business by any title it may please him to invent, but from the use of the word "Architect" he will be debarred entirely. And this only because he so elects. There are no hindrances placed in his way should he desire to enroll himself in our ranks.

If on the one hand he decides that he will follow the practice of his profession calling himself a "Designer," "A Plan Maker," or anything else, other than an Architect, well and good, no man will say him nay. It is entirely his own business and we may suppose he knows his own business best.

If on the other hand he wishes to use the more honourable title, all he has to do (if he be practising at the time the Act goes into force) is to send in his name and register as a member of the Association.

The Act says, "Any person now practising the profession of Architecture within this province may become a member of the Association by causing his name to be registered with the Registrar of the Association within three months of the coming into force of this Act and by paying to the Registrar such fee as may be made payable in that behalf subject to the proviso hereinafter contained."

Certainly no one can say that any difficulties are created; no man's rights, interests, or privileges are interfered with. If a man does not choose to register it is his own lookout. He can still continue to carry on his business, he can still charge his usual fees, and he can still collect them, all just as usual, only he cannot call himself an "Architect."

No difficulty will however arise from this source for I am proud to say that our Association practically numbers among its members every person following the profession of Architecture in the province of Ontario; if there are any whose names do not appear upon the roll it is owing to inadvertence of some sort and not because of any hostility to the proposed measure.

I am glad to state that we have had no dissentions within our ranks. Almost to a man the whole profession is in favour of the Bill.

It must not be forgotten that the present benefits (should the Bill pass) will be small, so small indeed as to appear almost insignificant. It is to the future we must look if we wish to see the results we hope for. Don't let any of us run away with the idea that just as soon as this Act comes into force something wonderful is going to take place. Nothing will happen at all. Business will be neither better nor worse. We will have just as much bother and just as much worry as ever. Work will be no more plentiful than it is at present and it will be no easier to get. It will be just as difficult to collect our fees as it is now. The modest man who only charges three per cent. will not suddenly find that he is going to have five per cent. thrust upon him. Not at all. These things will always be; they are not to be remedied by the passing of Acts. We will have only the consciousness, and it will be a very pleasant consciousness, that at last we belong to a profession which has some real and proper standing of its own, and that it lies with us to see, that in the time to come when the public find a man calling himself an Architect, they may know that he belongs to an honorable and recognized profession, and that he has acquired the right to wear the title by education, by reading, by work, by application and study, and finally by successfully passing such examinations as will be at any rate, some guarantee to the world at large that he is properly qualified to practice, and is learned in the science of the profession he has undertaken to follow.

I say science designedly, for it is that side of the education of an Architect which these examinations will go furthest to foster, and which, moreover, is most necessary for the safe guarding of life and limb. I put little, if any stress on the artistic side. For the cultivation of that, by means of examinations I have personally no faith whatever. You will never make an artist of a man, who has not had born into him the divine gift of artistic and creative power, by putting him through examinations from now till the day of judgment, and no Acts of all the Parliaments and Legislatures in Christendom will give it to him. You can teach him, however, to put up buildings that will not fall down. You can teach him the science of construction, the property and strength of materials, their proper application and use, the principles and theory of sanitary science, of plumbing, heating, ventilation, and many other kindred matters, and you can so direct his reading and his study that when he is able finally to pass his examinations successfully and attains the right to assume the title of "Architect" and commence the practice of his profession the public may feel justified in considering that they will be safe in entrusting the expenditure of their money into his hands.

It is to this end it seems to me that these examinations should lead, that we should strive to turn out thoroughly educated well qualified practical men, learned in all that pertains to good safe scientific building construction in all its varied branches, for this is the point upon which the public want to be assured of most, and the one about which they are the least competent to judge. If we

can help them in this, the passage of the Act will be more than justified.

The whole benefit of the Act (if passed) will accrue both to the profession of Architecture, as well as to the general public, in the future (and by no means in the immediate future)—not in the present.

It is framed almost entirely in the interests of the young men who are just now entering, and who will continue to enter the ranks of the profession. It is to insist that they shall educate themselves thoroughly and properly for the work they shall eventually be called upon to carry out, and to induce them to take advantage of the various means of study which are so reasonably and liberally offered to them. They can enter the office of some member of the Association in the ordinary way, serving a certain number of years under indentures, or they may graduate from the School of Science (curtailing by so doing the period of office work) but all shall be required to offer themselves for examinations to be held from time to time and pass each and all of them successfully before being permitted to register and practice under the title of Architect.

The Government has only recently established a chair of Architecture at the School of Practical Science. The Association can help greatly in making this Department a success and I can say without a doubt that we are most anxious and most desirous of assisting it by every means in our power. As things are at present, however, it is easy to see that there is little to tempt the ordinary young man to spend the time and money necessary to take the course if, at the end of it, he will occupy in the eyes of the public no better position in the profession to which it leads than that of any other youth who may have passed a year or two wandering from one office to another, or a builder's foreman who aspires to dub himself a professional man, or an auctioneer, or an undertaker, or anybody else who chooses to stick up his shingle and call himself an Architect.

It is only the very exceptional student who will avail himself of the great advantages of the School, and as the supply of exceptional young men is limited in all walks of life, the number of students at the School (if things remain as they are) will necessarily be much curtailed.

The Government must surely wish to see the School succeed—else what on earth was the use of their spending the money wherewith to start it, but if young men are to be induced to enter it at all it must be clearly shewn that it is to their advantage, (and by advantage I do not mean merely the advantage which a man gains over his fellows by means of a more thorough education) but it must be shewn also that the profession which they intend entering (and to which the course they are taking at the School is merely a stepping stone) carries with it a title which will give them a definite standing in the community—that it is a profession which can only be entered by men who have devoted much care, time and attention to their education and to the acquiring of that special knowledge necessary to the satisfactory practice of their calling. I say most unhesitatingly that the Government will discover that these young men having taken the time, and having gone through the labour and exertion of preparing themselves for the necessary examinations, and having passed them successfully, will expect, and very properly, and very naturally, expect, that they will find themselves in a somewhat different position, in that profession, for the practise of which they have spent so much labour and time in preparing themselves, from that occupied by a man who may have given himself no further trouble than having a sign painted.

We follow the shorter road rather than the longer as a rule. The public does not concern itself greatly as to the manner of education previously followed by men who have hung out a sign in hopes of attracting business. Anyone or everyone can, at present, if he so choose, call himself an Architect, and there exists no means by which the public can know whether he derived the title by working through the School of Architecture or by working through a saw-mill—it's all one to them, until something happens, and then the whole profession suffers.

The thing is ridiculous and absurd, and neither the profession nor the School can possibly be the success they might be until things are altered.

We should like above all things to make the young men go through the course of education which is necessary, but we have no means of compelling them. A good deal is done by persuasion and by shewing them the advantages which they will undoubtedly reap in the future. The few who do take the advice and prepare and offer themselves for examination deserve great credit.

But unfortunately the number (at no time as large as it should have been) is growing smaller. They find it irksome and only the enthusiastic ones persevere; the rest become disheartened and drop off. "What is the good," they say, "So-and-So has been studying in an office for a year or two and now he has started up in business for himself, has got several things to do and calls himself a full-fledged Architect. What's the use of my staying away for four or five years and working up a lot of examinations, when so far as the public can tell there's no difference between us."

It is foolish I admit, but it is not unnatural, and the consequence is that the country is being flooded with a lot of half-educated young men calling themselves Architects who can many of them make pretty drawings and sketches, but who can have never in all their lives done any real good honest hard work in reading up the perhaps somewhat dry, possibly uninteresting, but nevertheless absolutely necessary, practical and scientific side of the education of an Architect, (a side which cannot possibly be neglected without very great, and possibly very serious detriment, to the interests of their future clients.)

This Bill would in a large measure stop all this, as students would have to work properly at the practical side of their professional education in order to successfully pass their examinations.

If they did not choose to do so, if they were too lazy, too idle, or too incompetent, why then they would drop out and follow some other walk in life. Or should they see fit notwithstanding their failure, still to pursue the practice of Architecture they would be at perfect liberty to do so, there would be nothing to stop them nor would the Act interfere with them in any way, that is so long as they did not presume to use the title "Architect." That honorable appellation would be reserved for such only as have prepared themselves for the responsibilities of the position by a steady course of honest conscientious study, and that is what after a lapse of fifteen or twenty years the title of Architect will come to mean in the eyes of the public, a distinction by which men can tell the difference between one who has been properly and scientifically educated for his calling in life and one who has picked up such knowledge as he may possess at hap-hazard. Surely, gentlemen, this is not asking much at the hands of any Government.

To us of this generation the passing of the Act can make little if indeed any difference, save that as the years go on the young men will come into the arena better equipped, better educated, and therefore more formidable rivals to the older men who had not in their day the advantages now at the hands of the younger ones.

It is the students of to-day and the public of the future who will reap the fruits of our labours. Certainly we who are moving in the matter can be held guiltless of self-seeking, for of any actual personal immediate advantages there are none. Of a truth it may be said that we are sowing where we shall not reap.

All this I am afraid you will say is going over old and familiar ground, and I feel tempted to apologize for taking up so much of your time with it. But I cannot help feeling very seriously that the importance of it to the very life and existence of the Association is so great that it cannot be traversed too often. I want very much to bring it home to all of you that it is absolutely necessary, in order that we may be able to discuss the question thoroughly, that we should have the whole details of this proposed legislation at our finger ends, and be thoroughly conversant with every phase of it. It is the one great thing we must succeed in carrying out if the future work of the Association is to be crowned with success.

There is still time before the House meets for all of us to do something towards familiarizing the members of the Legislature with our aims, and I shall not I am sure appeal in vain to this Association when I ask them to do all they can in that direction.

Owing to various circumstances, the Act could not last year be introduced until almost the close of the session and it was felt to be unwise to court a possible defeat by bringing it up at a time when full discussion could not have been given to it or the members of the House made fully conversant with all its details. On the advice therefore of our friends in the House we decided to withdraw it.

It is hoped that this year it will be presented early in the session, but before that occurs it will be necessary for us to see that if possible every member of the Legislature is thoroughly informed personally of the details of the measure. If this is done it is hardly possible to imagine that any active opposition to its passage can be offered.

I have occupied so much of your time with this question of Legislation that I fear to try your patience longer, but I should like to say something about what is usually called the ethics of the profession. We hear a lot about ethics. It is a fine high-sounding term most frequently employed when one Architect thinks another has charged less than the usual five per cent. commission. Then the injured one gets on a pedestal and talks ethics. It sounds well and means nothing. It is a sort of architectural form of swearing, for one hears it most when there has been a row of some sort and this row is almost invariably about money matters of one kind or another. Or the injured man writes to the Council asking what they are going to do about it, for it seems to be thought in some quarters that this Association is a sort of trades union and that everybody belonging to it does and must charge all their clients nothing less than the acknowledged tariff list of fees.

I am afraid also that by some it is considered that the legislation we are seeking will in some mysterious way give to every man the legitimate scale of fees whether he will or no. Anyone indulging in that view is going to be disappointed. The legislation asked for, or any other legislation, will never do that for us. We are going to collect the same fees we have always done: neither more, nor less. The passing or the non-passing of the Act will make no difference whatever in that respect. This Association does not say anywhere that every man belonging to it is bound to charge the full fees, and on that ground nobody can blame any member who is foolish enough (or honest enough as the case may be) to ask less than the tariff allows him. The Council have been asked from time to time questions on this subject and have had complaints made that this member or that member is doing work for less than the usual rates. The Council can do nothing in such matters, nor can they take cognizance of any such complaints. There is a table of fees, certainly, which architects are in the habit generally of following, but that list was in existence long before this Association was formed. Members of this Association can adopt it or not just as they deem fit, but the Council have no power to compel them to do so.

This Association is not a Court of Justice, it is not inaugurated as such nor was it ever intended to be anything of the kind. The council does not sit in order to hear charges brought by one member against another with respect to the fees he asks or as to the manner in which he chooses to conduct his business.

True, a member can be expelled for gross unprofessional conduct upon a definite charge being laid and the proper method of procedure gone through, but that clause I take it means that the charge must be of such a nature as involves dishonest dealing towards his clients even though it is not actually punishable by law. It was certainly never intended that we were to have power to punish, expel or fine a member simply because he carries on his business in a way, innocent enough perhaps so far as the public is concerned, but which might not commend itself to the members generally as embodying the highest code of ethics.

I cannot, for the life of me, see why there is all this growling and grumbling about other men's fees. A great deal more practice of ethics and much less talk would be better for all of us. If one man chooses to charge his clients three per cent., another two-and-a-half per cent., another four, and another five, why on earth should anyone complain? The men in question evidently think that that is what their respective work is worth. They are the best judges of its value and in that respect they are honest. I do not see, indeed, why a man should not, if he see fit, advertise that he is a three per cent. architect, or a two-and-a-half per cent. man, or a four per cent. man, ar anything else he thinks his work is worth; he might put it on his letter paper or on his visiting cards or anywhere else. It is his own business; why should anybody mind, that is, so long and only so long as he charges everybody the same. But the individual this Association ought to mind, and ought to frown down in the severest possible manner, and moreover punish (if a way can be found), is the man who adopts a sliding scale of fees for the same class of work. The man who fixes his scale of fees lower than the recognized tariff and having fixed it sticks to it is not the one most guilty of transgressing the ethics of the profession. He may be foolish, but he is honest. But it is the man, who for the same class of work varies his charges, who gets out of one man five per cent., because he is a decent sort of fellow; out of another three per cent. because he is a hard-fisted chap who always drives a close bargain; out of another, two-and-a-half per cent., because if he charges more somebody else will get the work; who is guilty of the grossest form of unprofessional conduct. The other man errs certainly, but to no serious extent. He may say "It's all very well for so-and-so to charge the full fees for everything he does, but I'm not in that position and can't get them!" Very well, that's his misfortune, possibly his fault, let him lower his scale to four, to three, to what he thinks wise, and subdivide that scale in the same proportion as the usual scale of five per cent. is already subdivided, and having done this let him stick to it; nobody can accuse him, at any rate, of dishonesty.

But the other man is dishonest, dishonest both to the profession and to his clients. For instance, A comes to me and commissions me to build a house for him to cost $20,000; he is a gentleman and a descent fellow willing to pay properly for what he gets, and so leaves it to my honor to charge him what the work is worth. Consequently I bill him for $1,000 or five per cent. upon the cost, being the fee I am usually in the habit of charging. Then comes B for whom I do exactly the same work—a house costing $20,000—but B is a hard fisted man who loves to drive a close bargain and so, by reason of that, and for fear that if I do not come down in my charges he will take his work elsewhere, I agree to do it for three per cent. and send him in a bill for $600. Unfortunately A and B meet, they talk about their new houses, and in the course of their conversation the matter of my charges comes up, and it is discovered that I have charged A $400 more than I have charged B, and for identically the same work.

What would A think of me, and what possible explanation could I offer him? Could I feel hurt if he went about complaining that I had swindled him, and could I persuade anybody that my conduct had been that of an honourable man?

It is against this sort of unprofessionalism which we must take the greatest care to guard ourselves. Any conduct on the part of an architect, which, while an offence against his brethren is even more so as regards his clients, must be put a stop to, if the profession of an architect is ever to obtain the honourable position it deserves.

But there is a great deal more in the Ethics of the profession than this everlasting miserable question of money and charges. There is good manners and fair dealing one towards another, consideration of one anothers' work and one anothers' feelings. There might be less backbiting and more generosity, more sympathy for each others' failures and less jealousy about one another's successes and more kindness and cordiality all round, but do, for the sake of all that is decent, let us put an end to these perpetual accusations of unfair and unprofessional conduct which are so constantly being bandied about. If there is nothing in the profession except the money we can make out of it, we had better abandon it, break up the Association and take to some other calling for the chances of fortune in the practice of architecture are few and far between.

I have occupied so much of your time with this question of legislation that I can say but little else, indeed I do not know that there is much that need be said. Matters of purely professional interest will be taken up by the various gentlemen who have been kind enough to prepare the papers which will be read to you. Financial matters will be dealt with by the Secretary and Treasurer. I have confined myself almost entirely to the one real vital question which at present most concerns the very existence of this Association.

I thank you gentlemen, for your attention here to-day, and we may now proceed to business.

The reading of the address was received with every manifestation of approval, and its conclusion was the signal for prolonged and hearty applause.

TREASURER'S REPORT.

Mr. H. B. Gordon then read the report of the Treasurer, as follows:

THE TREASURER IN ACCOUNT WITH THE ONTARIO ASSOCIATION OF ARCHITECTS.

1895	Dr.	
Jan'y. 1st	To balance from 1894	$1,780 00
Dec. 31st	Members' Annual Fees	214 00
"	Members' Registration Fees	30 00
"	Students' Registration Fees	18 00
"	Students' Examination Fees	19 00
"	Sale of Examination Papers	25
"	Interest on Treasurer's Bank Acct., 1895	56 08
		$2,117 33

1895	Cr.	
Dec. 31st	W. A. Langton, proportion of Salary paid in 1895 as Registrar and Librarian	$273 71
"	W. A. Langton, General Disbursements	28 07
"	Travelling Expenses, Member of Council	6 50
"	Caretkr. Sch. P.S. re Convention and Exams.	15 00
"	H. Webb, Luncheon for Convention	15 00
"	C. H. Mortimer, ½ cost reporting Convention	22 50
"	N. R. Butcher, Typewriting	12 70
"	Printing Reports and Circulars, etc.	56 60
"	Printing Examination Papers	25 00
"	General Stationery	14 10
"	Book added to Library	3 35
	Total Disbursements	$ 472 53
"	Balance on hand	1,644 80
		$2,117 33

We have examined the books, vouchers, etc., of the Association, and certify that the above is a correct statement thereof.

WM. R. GREGG,
M. B. AYLSWORTH.

STATEMENT OF ASSETS AND LIABILITIES, JANUARY 1ST, 1896.

Assets.		
Cash in Bank		$1,644 80
Library as per Valuation		
Unpaid Membership Fees:		
1891 ..... 6 Fees	$ 28 00	
1892 ..... 16 Fees	200 00

		$2,463 80

Liabilities.	
Half Year's Salary, Registrar and Librarian	$ 150 00
Outstanding Accounts	33 60
Balance	$2,280 20
	$2,463 80

H. B. GORDON, Treasurer.

On motion by Mr. Dick, seconded by Mr. Wickson, the Treasurer's report was received and adopted.

REPORT OF REGISTRAR AND LIBRARIAN.

The following report was then read by the Registrar, Mr. W. A. Langton:

REPORT OF THE REGISTRAR AND LIBRARIAN AT THE ANNUAL MEETING ON JANUARY 14TH, 1896.

MEMBERS.

The Annual Register of members for 1895 contained 133 names. One member has since died. The 132 members remaining on the roll are classified as follows:

Class	I.—Practising in York County, 5 years and over	48
"	II.—Practising in York County, under 5 years	4
"	III.—Practising in cities outside of York, 5 yrs and over	38
"	IV.—Practising in cities outside of York, under 5 years	4
"	V.—Practising in towns, villages, etc.	17
"	VI.—Civil servants	12
"	VII.—Not practising in Ontario	9
		132

NOTE.—The number of members in Classes II and IV is variable, and is established by application for the rebate by those who are entitled to it when paying their fees. In the above list the number fixed for these classes is the number of those who have applied for the reduced fee in 1895.

STUDENTS.

Students consist of those called by the Act "existing students" and of new students. Existing students were those who had been articled before the Act was passed and were required only to pass the final examination of the Association before being allowed to register as Architects. Many of these had already served their time—sometimes a considerable time before—but were still working as draughtsmen. The number of existing students registered was 82. The greater part have drifted away to other parts or to other callings, and some are practising architecture without having registered as architects, but there are several still in touch

with the Association. Of these 17 have passed the final examination, 7 subsequently registering as architects, and 1 was admitted to registration as an architect after having passed the examination of the Royal Institute of British Architects.

Of new students the roll is as follows :—

Registered in	1890	9
"	" 1891	6
"	" 1892	11
"	" 1893	6
"	" 1894	2
"	" 1895	2
		—36

These students are nearly all in communication with the Association and seem to be following out its curriculum.

The Board of Examiners for 1895 were :

PROFESSOR GALBRAITH, Principal of the School of Practical Science, Chairman ; Mr. C. H. C. Wright, Lecturer in Architecture at the School of Practical Science, and the following members of the Association : Messrs. Aylsworth, R. J. Edwards, W. R. Gregg, Helliwell, Symons, Townsend and Wickson.

The examinations held this year were as follows :

	No.	Passed.	Plucked.
First Intermediate	3	2	1
Second "	7	3	4
Final	4	1	3

PROCEEDINGS OF THE COUNCIL.

Pursuant to the action of the Convention with regard to improved Municipal building and fire by-laws, a Committee of Toronto Architects, nominated by the Council, drew up a complete set of building by-laws and submitted them to the Mayor and Council of Toronto.

The proposed exhibition of architectural drawings was held in connection with the exhibition of the Royal Canadian Academy, the drawings being contributed to the Academy exhibition and forming the architectural department of the exhibition.

A competition was instituted for drawings of the students' diploma which at the last Convention it was decided to issue. The drawings submitted in competition were not satisfactory. A skilful draughtsman, who is a student of the Association, subsequently agreed to furnish a drawing and is engaged now in completing it.

The most important work of the Council during the year was the endeavor to procure legislation amending the Act of Incorporation. Some difficulty was found in introducing the bill because of the antipathy which has arisen to giving independent power to corporations, and our bill when at last introduced was too low on the list to come on for debate in that session. It is now, however, ready for introduction on the earliest possible opportunity at the next session. It has been discussed with the party principally opposed to giving uncontrolled power to corporate bodies, and in its present state meets with no opposition from that portion of the House. There seems every reason to believe that the bill is now in a position to meet with a fair hearing, and it has been found hitherto that public men who have had opportunity to give it a fair hearing have agreed that it would be a useful measure.

THE LIBRARY.

There has been one book added to the Library—a necessary text book.

There have been 129 lendings, or 18 more than in 1894.

W. A. LANGTON,
Registrar and Librarian.

On motion by Mr. H. B. Gordon, seconded by Mr. Rastrick, the report was received and adopted.

The President then suggested the discussion of any business arising out of the reports.

Mr. W. R. Gregg inquired as to what had been the result of the action taken by the Committee appointed at the last Convention to communicate with the city authorities in regard to amending the then existing by-laws ?

Mr. Gordon stated that several of the gentlemen composing that committee had attended several meetings, and at the cost of no inconsiderable amount of labor had at last succeeded in preparing a complete by-law. In the meantime they had apprised the City Hall authorities that they were engaged upon such a work, and, knowing that preparations were being made for the re-building of some of the edifices destroyed by the disastrous fires which had occurred shortly before, some of them buildings of great extent, and fearing that before they could lay their views in full before the city authorities, permits might be issued for the erection of some of these buildings, without the necessary restrictions which were under discussion, they had submitted an interim communication, presenting those points which the committee regarded as most urgent, and asking the city council to adopt them in the meantime, until they should be supplemented by the complete by-law when the committee completed its labors. The points submitted were discussed by the city committee on Fire and Light, and to some extent adopted, but at the same time some very vital points were not adopted, evidently because very strong interests were brought to bear in opposition to the object the architects' committee had in view. Those desirous of spending the minimum amount of capital and wishing to erect large buildings with undivided areas, and so on, at the very cheapest rate, had been able to so influence members of the city council that the object of the architects' committee was to a large extent defeated. They did, however, succeed in some points, some amendments that were desirable being made to the by-laws, and although the labors of the committee had not brought forth all the results anticipated, he thought two results had been accomplished. First, they had demonstrated to the members of the city council, the fire underwriters, and others, that the Association of Architects was interested in the matter, and fully alive to the necessity of the changes, and that they had gone to a great deal of trouble in order to present their views in a shape convenient to be legislated upon, and, secondly, the action taken had had the effect of bringing the Association more prominently before the public, and presenting in a very effective and tangible form the benefit to the general public of having such an organization in existence.

Mr. H. Paull said he noted in the minutes that any surplus over the expenditure was to be applied to the purchase of books for the library, and he learned from the report of the Librarian that during the year only one book had been purchased.

Mr. Langton explained that the book purchased was a work which was a necessity, but, as a matter of fact, there had been no surplus to apply to that object.

Mr. Gregg called attention to the fact that a committee had been appointed last year to advocate municipal improvements.

Mr. Langton said that the members of that committee were largely from outside of Toronto, Mr. Dick and Mr. Aylsworth being so far as he was aware, the only city members.

Mr. Dick said he was not able to make any report ; he did not remember having received notice of any meetings of the committee in question.

Mr. Langton said he had conversed with Mr. Aylsworth once or twice during the year on the matter, and they had been agreed in believing that the committee could not call a meeting of influential citizens except for an obvious occasion. Their idea was to find some influential person who would become interested in the matter to inaugurate the movement. They had been unable, however, to fix upon any suitable person who would be likely to accept the responsibility.

Mr. W. R. Gregg thought it was very important that this matter should not be lost sight of or allowed to drop, and suggested the retention for the coming year of the same committee, with some additional members, residents of Toronto.

After some further discussion Mr. Gregg moved, seconded by Mr. Townsend, that the said committee be continued for the coming year, with power to add to its numbers. (Carried.)

Mr. Langton said that he had been the mover of the resolution under which this committee was originally created, and that the idea was not that the committee should be expected to accomplish the desired objects within any limited time, but that the objects to be attained were of such a nature that the Association ought to be interested in them, and there ought to be a committee alive ready to act when any favorable opportunity presents itself ; which end would be attained by the resolution just passed.

Mr. Rastrick asked if the resolution applied to the members in outside places, that is, could the members in other places add to their numbers.

The President replied that he understood the resolution to practically have that effect.

Mr. H. Paull suggested the advisability of securing the co-operation of the Canadian Institute, the professors of the University, or any other body which might assist in forming a larger committee, which might influence the municipal authorities.

Mr. Gregg said that under the present resolution the committee had full discretionary power to do anything of that sort which they deemed desirable.

The President thought that the committee was not restricted in its line of action, but could deal with any matter that might arise without anything further being said.

Mr. Burke suggested the advisability of tendering the assistance of the Association in improving the Island Park, in the way of giving advice.

Mr. Gregg said there was a point which was lost sight of last year, the rounding of the corners of Queen and Yonge streets. Had the committee been a very active one perhaps both the corners in question might have been rounded instead of only one.

Mr. Burke pointed out that many opportunities for improvement would be lost unless someone took the initiative, as was the case in regard to one of the corners spoken of, where it was only because of the lack of interest to push the matter that the improvement was not made.

Mr. Pearson, reverting to the subject of the committee on improvements in the building by-laws, expressed himself as not quite satisfied with the report made by Mr. Gordon. He himself was left quite in a maze as to what had been done with the by-law submitted, which seemed to have been taken to the City Hall and there pigeon-holed. He would like a little further information as to what had been done in that matter.

Mr. Gordon said the city authorities had adopted parts of the by-law recommended, and had patched up the old by-law. Of course the by-law submitted by the committee was to some extent a reiteration of much that was in the then existing by-law, only put in a clearer and more concise form, and in some instances with increased stringency. He did not think the matter was by any means a dead issue, and as a result of a paper he proposed reading before the Association during its present sessions he hoped to see, not only in Toronto, but also in outside towns and villages, permanent committees appointed for the purpose of having proper municipal by-laws passed.

The President said that probably the matter was lying in statu quo.

Mr. Gordon replied that that was the case to a certain extent ; it could not be expected that the suggestions made would be adopted in their entirety, because at the City Hall there were so many other things to be considered.
